  - RM mentioned that EPA has some uncommitted funding available and is considering using it to perform some geophysical testing at LHAAP-18/24. RMZ cautioned about the timing and potential problems that may occur if it is conducted while the PBR

solicitation is outstanding. Before starting any work, RMZ requested further discussion with RM.

- Monthly data – See attached December 2016 Validated LHAAP Data
- Groundwater Treatment Plant Operations – Discussed earlier in Item 17-1.

MMRP Update **Army**

- No update

Other Environmental Restoration **Army**

- Quarterly Reporting and Requirements – These items were already discussed (see summaries in the DERP PBR Update section.
  - GWTP Evaluation
  - Surface Water/Perimeter Well Quarterly Update
  - Administrative Record Update
  - Website Update
- Annual Reporting
  - LUC Management Plan Update - Signed Revision Log and transmittal letters will be entered into the 2016 Q4 AR update.
  - CRP/CIP Revision (Biennial) – RMZ asked NS if there was any update on the CRP; NS responded that there is not.

USFWS Update **RMZ/PB**

Schedule Next Managers' Meeting

- February 2017 MMM will be held by teleconference on 2/23/17 at 10:00 am CST.

Adjourn

Attachments:

- **December 2016 Validated LHAAP Data:**
  - GWTP Effluent: Weekly, Bi-weekly, and Monthly Sampling (November 2016)
  - GWTP Influent: Monthly (November 2016)
  - LHAAP-50: Semi-annual MNA Sampling (November 2016)
  - SW/PER: Surface Water/Perimeter Well Sampling (November 2016)

ACRONYM LIST

AEC	United States Army Environmental Command
AECOM	AECOM Technical Services, Inc.
AP	April Palmie
AR	Administrative Record
AW	Aaron Williams
BF	Barry Forsythe
BRAC	Base Realignment and Closure
CH	Craig Holloway
CIP	Community Involvement Plan
CRP	Community Relations Plan
CST	Central Standard Time
DERP	Defense Environmental Restoration Program
DH	Dorelle Harrison
DR	Debra Richmann
EPA	United States Environmental Protection Agency
ES	Elspeth Sharp
FBR	Fluidized Bed Reactor
FS	Feasibility Study
GH	Glenn Hilton
GWTP	Ground Water Treatment Plant
HB	Harrison Bayou
HCl	Hydrochloric Acid
ICT	Interceptor Collection Trench
IDW	Investigation-Derived Waste
JS	JoLynn Snow
LHAAP	Longhorn Army Ammunition Plant
LTM	Long-Term Monitoring
LUC	Land Use Control
MMM	Monthly Managers' Meeting
MMRP	Military Munitions Response Program
MNA	Monitored Natural Attenuation
NS	Nick Smith
O&M	Operation and Maintenance
PB	Paul Bruckwicki
PBR	Performance-Based Remediation
PDI	Pre-Design Investigation
PSI	Post-Screening Investigation
RAB	Restoration Advisory Board
RACR	Remedial Action Completion Report
RA-O	Remedial Action Operation
RAWP	Remedial Action Work Plan
RC	Randy Cerar
RD	Remedial Design
RFP	Request for Proposal
RI	Remedial Investigation
RM	Rich Mayer

RMZ	Rose M. Zeiler
ROD	Record of Decision
RTC	Response to Comments
SAP	Sampling and Analysis Plan
TBD	To Be Determined
TCEQ	Texas Commission on Environmental Quality
USACE	United States Army Corps of Engineers
USFWS	United States Fish and Wildlife Service
WP	Work Plan

LHAAP Data Validated
December 2016

GWTP Effluent *Weekly, Bi-weekly and Monthly Sampling - November 2016*

Ammonia (350.1)	Metals (6010C)
Ortho-Phosphate (365.2)	Metals (6020A)
Organic Carbon (415.1)	Hexavalent Chromium (7196A)
Perchlorate (6850)	VOC (8260B)
1,4-Dioxane (8270D-SIM)	Anions (9056)

GWTP Influent *Monthly - November 2016*

Perchlorate (6850)
VOC (8260B)

LHAAP-50 *Semi-Annual MNA Sampling - November 2016*

Alkalinity (310.2)	VOC (8260B)
Phosphorus (365.4)	Anions (9056)
TOC (415.1)	Dissolved Gases (RSK-175)
Metals (6010C)	Sulfide (SM-4500-S-(-2)-F-2000)
Metals (6020A)	
Perchlorate (6850)	

SW/PER *Surface Water/Perimeter Well Sampling - November 2016*

Perchlorate (6850)

GWTP Effluent Weekly Sampling - November 2016

Location ID: / Sample Date:	Units	Daily Maximum Conc	LH18/24-SP650-6408-GRAB 11/7/2016	LH18/24-SP650-6410-GRAB 11/14/2016	LH18/24-SP650-6411-GRAB 11/21/2016	LH18/24-SP650-6413-GRAB 11/28/2016
Location Description:			GWTP–Collected from a spigot on the discharge of effluent TK-650. Sampled Weekly.			
Ammonia as N (350.1)						
AMMONIA AS N	mg/L		11.8	7.26	10.7	16.6
Ortho-Phosphate (365.2)						
ORTHO-PHOSPHATE	mg/L		2.82	1.9	2.42	2.93
Organic Carbon (415.1)						
TOTAL ORGANIC CARBON (TO	mg/L		49.8	29.1	47.8	52.6
Perchlorate (6850)						
PERCHLORATE	ug/L	13	18.4	6.62	1.26	<0.2 U
Semi-Volatile Organic Compounds (8270D-SIM)						
1,4-DIOXANE*	ug/L	134.2	19.4	14.6	24.1	25.3

* Calculated Effluent Limit

mg/L - milligrams per liter

U - Undetected: The analyte was analyzed for, but not detected.

ug/L - micrograms per liter

GWTP Effluent Biweekly Sampling - November 2016

Location ID: / Sample Date:	Units	Daily Maximum Conc	LH18/24-SP650-6409-COMP 11/14/2016	LH18/24-SP650-6409-GRAB 11/14/2016	LH18/24-SP650-6412-COMP 11/28/2016	LH18/24-SP650-6412-GRAB 11/28/2016
Location Description:			GWTP – Collected from holding jar accumulating aliquots of discharge from a TK-650 effluent spigot every few hours. Sampled Biweekly.	GWTP – Collected from a spigot on the discharge of effluent TK-650 Sampled Biweekly.	GWTP – Collected from holding jar accumulating aliquots of discharge from a TK-650 effluent spigot every few hours. Sampled Biweekly.	GWTP – Collected from a spigot on the discharge of effluent TK-650 Sampled Biweekly.

SULFIDE	mg/L		NA	<1 U	NA	<1 U	NA	NA	NA	NA	<1 U	NA	<1 U

Blue Highlighting Indicates concentrations above the MCL/PCL/UTL

Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

Metals results for "FF" samples are dissolved.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Limit

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Risk Reduction Program (TRRP) Tier 1 Groundwater Residential Protective Concentration Level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

UTL - Upper Tolerance Limit

SM4500-S-(-2)-F-2000													
SULFIDE	mg/L		NA	<1 U	NA	<1 U	NA	NA	NA	<1 U	NA	NA	NA

Blue Highlighting Indicates concentrations above the MCL/PCL/UTL

Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

Metals results for "FF" samples are dissolved.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Limit

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Risk Reduction Program (TRRP) Tier 1 Groundwater Residential Protective Concentration Level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

UTL - Upper Tolerance Limit

LHAAP-50 Semi-Annual MNA Sampling - November 2016

Re: Final Revised Feasibility Study for LHAAP-18/24, Burning Ground No. 3 and Unlined Evaporation Pond at Longhorn Army Ammunition Plant, Karnack, Texas, January 2015

Dear Mr. Mayer,

As discussed during the January Monthly Manager's Meeting, the above referenced document will be considered the final version based on the resolution of agency comments during a conference call held on 12/14/16 and acceptance email on 12/16/16. Amended Comment Response Matrices documenting Agency concurrence with the Army's responses are attached for your file.

The document was prepared by AECOM on behalf of the Army as part of AECOM's Performance Based Remediation contract for the facility. I ask that Debra Richmann, AECOM's Project Manager, be copied on any communications related to the project.

The point of contact for this action is the undersigned. I may be contacted at 479-635-0110, or by email at rose.m.zeiler.civ@mail.mil.

Sincerely,

Rose M. Zeiler, Ph.D.
Longhorn AAP Site Manager

Respondent: Debra Richmann and Doug Gray, AECOM

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
1	Page VI	Acronyms and Abbreviations	(a). Please add DCE to the list (first use on page xiii). (b). Please add TSD to the list (first use on page 1-3) (c). Please add SDWA to the list (first use on page 3-4). (d). Please add ASTM to the list (first use on page 4-20) (e). Please remove FR from the list, since it is not used in document.	C	(a). Removed cis-1,2-DCE and replaced with DCE – dichloroethene – in the list of Acronyms and Abbreviations. (b). Added to the list of Acronyms and Abbreviations. (c). Added as above; also SDWA is first used and defined) on page 2-2. (d). Added as above; also added definition at first use on page 4-20. (e). FR not removed from list since it is used in the document (first use on page 3-2), where it is now also defined.	A
2		Table of Contents	The electronic version of the table of contents is incomplete.	C	The partial TOC in electronic version has been replaced with the complete TOC.	A
3	Page XII		Please add references for Camp, Dresser, and McKee 1986 and Final Updated PSI AECOM 2016, to the reference page.	C	The references have been added to Section 7 – References (Note-Final Updated PSI Report is AECOM, 2016a).	A
4	Page XIII	Minor Editorial Comment	First use of MSC, please define in text.	C	Added definition of MSC to the text on first use.	A
5	Page XV	First paragraph		X	No comment provided.	A
6	Page 1-1	Section 1.1, First Paragraph	Please include references for the work conducted by the Army in 2013 and 2104 (PSI?).	E	The 2013 and 2014 investigation results are presented in the Updated PSI Report, which has been added to the references in Section 7 (AECOM, 2016a).The text in Section 1.1 has been revised accordingly.	A
7	Page 1-2	First Bullet	Please add AECOM 2015 reference to reference list.	C	The year of the reference in the first bullet, 2015, is incorrect. It has been corrected in the text (2016a) and added to the references in Section 7, as noted in the response to comment 6.	A

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
8		Table ES-1, Comparative Analysis of Alternative	For alternatives 2 and 3, EPA considers the timeframes (several hundred and 500 years) as being unreasonable.	E	Noted. However, as stated in the Alternative 2 text, because the use of groundwater as a water supply is unlikely based on future land use at LHAAP-18/24, the time frame to achieve groundwater ARARs could be considered acceptable. For Alternative 3, ARARs would be achieved in 20 years outside the containment, but would require an ARAR waiver for groundwater inside the slurry wall which is allowed under CERCLA if properly justified. No changes were made to Table ES-1.	A
9	Page 1-2		Please see the reference section for USACE, 1993. There are two USACE 1993 references, so please add an a and b to distinguish them.	C	Cannot find a USACE, 1993 reference on indicated page 1-2. There should only be one reference for USACE, 1993 in Section 7 – it is for the source documents used for Figures 1-8, 2-3, and 2-4, which show the Shallow Zone potentiometric surface and/or COC concentrations, based on November 1992 data. The full citation is already included in the References section. It is also identified on each of these figures and will be inserted in the text where these figures are introduced. The second USACE, 1993 reference in Section 7 has been removed, because it is not referred to in the revised FS.	A
10	Page 1-4	First Paragraph, Second Sentence	EPA agrees that there are no natural drainages within the containment area, but based on previous site visits there does appear to be surface drainages developed on the eastern side (developed during broken pipe) and in the northwestern corner (excessive sprinkling). Please revise.	C	Assume this comment refers to the first paragraph of Section 1.4. The following was added at the end of the referenced sentence: “, however, minor drainage paths have been observed in the northwestern part of the site, associated with intermittent ponding in low areas after heavy rainfall events”. The eastern side of the site is flat, and as such, any limited runoff is not channelized.	A

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
11		Figure 1-6 (EPA Comment No. 6 from PSI addendum)	Monitoring well MW-20 is known to be in a perched zone. The new well, 18CPTMW22R appears to be completed in the same perched zone. EPA recommends not using these wells for groundwater level contouring.	C	The figure was changed and the referenced wells were not used for shallow zone groundwater level contouring.	A
12	Page 1-6	Minor Editorial Comment, First Paragraph	Please see typo error about midway through the paragraph. Please remove "4".	C	The typo "4" has been deleted in the clean pdf document (it did not appear in the redline version).	A
13	Page 1-6	Section 1.6, Table 1-1	Please include all references in this section and table in the reference section (i.e., U.S. Army Environmental Agency, 1982 and etc.).	E	Some of the items included Table 1-1 are not actually documents, i.e., bulleted items describing activities included in primary reference documents, or are secondary references that were not consulted. Primary references that were used to develop this revised FS are included in Section 7 – References.	A
14		Figure 1-9, Minor Editorial Comment	Please check the explanation and legend on the figure to ensure what is listed is shown on the figure. In this case, FD and others are not shown on map.	C	FD, F, and UJ are not used in the figure, so were deleted from the explanation.	A
15	Page 1-7	Second Paragraph	Please include Shaw 2007 reference in reference section. There is already a Shaw 2007a and 2007b, but EPA believes the one mentioned in the text refers to a different document.	C	The reference for the pilot study, (Shaw, 2007c), has been added.	A
16	Page 1-9		The first use of GWP-ind, please define.	D	The first use of GWP-Ind is on page 1-8 (first bullet), where it is defined.	A
17		Figure 1-20	It is obvious that there has been a lot of effort in compiling the more recent and historical soil data. It would be helpful if the explanation has the year the data was collected for each soil sample. EPA recommends adding a label for the ACD on the map since the text references the area west and south of the ACD.	C	The year the soil samples were collected and the sources of the information have been added to Figure 1-20. The ACD is now labelled on the figure.	A

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
18	Page 1-9	First Paragraph	The text states that the water levels range between 3.41 and 6.25 bgs. in monitoring wells 120 and AWD-1 and that these are the natural groundwater table. As stated in previous comments on saturated soils at 18/24, both of these wells are in an area that is typically saturated by irrigation. The comparison of the water levels from the 1992 data does indicate water levels are within a few feet of the current elevation (PSI), but EPA would recommend being more conservative with the depths due to irrigation. What is more cost effective for the Army, soil removal or groundwater extraction and treatment? 12/16/16 Follow-on comment: "EPA agrees with the wording changes which depicts a more accurate condition of that region. EPA's point (from the last sentence of the comment) is that soil remediation is generally less expensive that groundwater remediation."	E	The statement "the impacted soil …is within the natural groundwater table fluctuations and is considered saturated soil" was modified to "is within the range of observed groundwater table fluctuations, considering seasonal variations and potential intermittent influences from irrigation at the site". With regard to cost effectiveness, the FS is intended to evaluate and identify potential remedial alternatives related to the entire site. Noted.	A [3]
19	Page 2-2	First Paragraph, Third to Last Sentence, Minor Editorial Comment	Please see minor typo error "discussion of".	C	A space was inserted between the two words. Also inserted "to" between "risk" and "a hypothetical …" in the same sentence.	A
20	Page 2-3	Last Paragraph	Have the values for dioxin and furans been updated to include EPA new numbers?	--	The values used to assess the carcinogenic risk of dioxin (2,3,7,8-TCDD equivalents) are shown in Table 2-1.	A
21	Page 2-9	Section 2.4.2.2	Please add ITRC, 2003 to the reference page.	C	The reference is listed in Section 7 as "The Interstate Technology and Regulatory Council". It has been re-named "Interstate Technology and Regulatory Council" and inserted alphabetically after the Gomes reference.	A
22	Page 2-16	First Paragraph	Please see spacing and typo error in the third sentence.	C	The spacing irregularities and missing text have been corrected. Also, in the second sentence, "liner" was changed to "layer".	A

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
23	Page 2-16	Last Paragraph, Second Sentence	EPA recommends mentioning that the mounding shown on maps from data collected prior to the IRA may be showing the effects of the unlined evaporation pond.	D	The UEP was closed by removing waste and installing a cap in 1986 well before 1992, thereby eliminating it as a source of enhanced recharge.	A
24	Page 2-16	Last Paragraph, Last Complete Sentence	"*The current depiction of the potentiometric lines in the Shallow Zone in the southern area of the site (Figure 1-6) consistently shows that there is no horizontal gradient to the south to facilitate migration of COCs outside the containment area*". It appears there is the potential for flow towards the southeast based on information depicted on Figure 1-6. Please clarify.	C	The text has been revised to replace "no" with "little", "…there is little horizontal gradient to the south to facilitate migration…" There is an element of flow from the high mounded area near 123 and AWD-2 to the south. However, the gradient becomes extremely flat near the southern corner of the site. Along with the extraction conditions in ICT 12A and ICT 11, little possibility exists for the contaminants to flow outside the containment to the south. It has been acknowledged in the revised text that monitoring well 18CPTMW22R is completed in a perched water zone and it was not used for contouring the shallow zone groundwater surface in revised Figure 1-6 (see response to comment 11). Therefore, the off-site groundwater high previously shown in this area no longer exists and with its removal, the previous apparent steep radial gradient off of the high is no longer present.	A

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
25	Page 2-17	Top of Page. Please see EPA Comment Number 6 from the PSI	*Well MW-20 is known to be in a perched zone. The new well 18CPTMW22R appears to also be completed in that small perched zone.* EPA recommends not using these wells for groundwater level contouring. If you follow this logic, then this would mean the perchlorate found in the southwest area did not come from onsite, which in previous text states the perchlorate did originate from onsite prior to IRA implementation. Is the intent to say the perchlorate in this area all migrated in from a deeper depth. Please clarify.	C	See response to Comment #11. See also the related text deletion at the end of the second to the last paragraph in Section 2.4.2.5.	A
26	Page 2-17	Second Paragraph	So far the report does not include any information about the injection and irrigation of the GWTP effluent which has an effect on groundwater levels in the containment area (especially in the northwest corner). In addition, historical data has indicated that the pumps have not been working on the north side, which would also contribute to the mounding. EPA recommends writing a few sentences to indicate that the pilot study and irrigation may be effecting the groundwater levels at different locations across the site.	D/C	The pilot study re-injection of groundwater was discontinued as of July 15, 2012 and therefore the effects would no longer be present. In Section 4.4.1.7.3 – Reinjection, the sentence before the first bullet has been replaced with the following: "However, reinjection of treated wastewater has not been performed at the GWTP since 2012 and resumption of the practice is unlikely due to potentially deleterious risks."	A
27	Page 2-18	Minor Editorial Comment, First Paragraph	Please see minor typo error "*18CPTMW04adjacent*".	C	A space was added between the well ID and "adjacent".	A
28		Table 2-11, Minor Editorial Comment	Please see minor typo error in notes at the bottom of the table "*The 2016 concentrations from ??? were used*".	C	Footnote was changed to "The concentrations from 2016 were used."	A

2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
29	Page 2-20	First Paragraph, Text References, Figure 2-6	The actual figure is marked as figure 2-6a. The text should introduce the figures 2-6a-c. EPA recommends using some other units besides exponential notation. The 3 rows at the bottom of the graphs appear to be yearly totals, but it is difficult to see the exponent. Please revise the figures.	C E	Figure numbers have been changed to 2-6a, -6b, and -6c respectively for perchlorate, TCE, and MC in the text and the LOF. The last three rows at the bottom of the graph have been deleted because the information is redundant. It is provided at the top of each annual bar.	A
30	Page 2-21	Section 2.4.3, Wilcox Formation Groundwater	EPA agrees with the saturated thickness within the Wilcox used to determine potential mass of the COCs. However, there are several locations as stated in the comments on the PSI where the vertical extent of the COCs is not known. In particular, MW-14 has had a detection of >200,000 µg/L in lower section of the screened interval. The concentrations below that location is unknown, so the mass estimates could be low. A secondary issue is that the ICT concentrations of COCs tend to be higher than in monitoring wells. Are the ICT concentrations being considered in the calculation in determining mass?	C	It is acknowledged that the mass estimates could be low in certain areas of the site. However, it is also noted that the high concentration in MW-14 is likely limited in aerial extent as illustrated by the low perchlorate concentrations in surrounding MWs screened in the Wilcox. Therefore while some underestimate of calculated mass may be possible with respect to the overall distribution of mass in the subsurface the current estimate is believed to be suitable for use in evaluating the various potential remedial alternatives in this area of the site. The first complete sentence in the paragraph at the top of page 2-23 states: "For every one (1) foot increase in impacted thickness, the dissolved mass would increase by a factor of ~5%, assuming the groundwater concentrations remain unchanged." The ICT concentrations are used for determining the mass of COCs recovered, but the estimates of dissolved phase mass are based on the isoconcentration contours for the respective COCs, as depicted in the associated figures in the FS.	A
31	Page 2-23	Last Sentence	The first use of UCL. Please define here.	C	The definition – upper confidence limit – has been added.	A

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
32	Page 2-24	First Paragraph, Second Sentence	EPA recommends deleting the sentence since it compares mounding between 1992 shallow groundwater and 2016 Wilcox aquifer wells. The mounding for 1992 is located in a different location and second there was very little data collected in the Wilcox until recently.	C	The second sentence has been deleted.	A
33	Page 2-25	Section 2.4.4	The text states an effective porosity of 25 percent was used. This value seems to be high for the effective porosity since the Wilcox is predominantly fine grained. Are there geotechnical data to support the use of the 25 effective porosity? It appears the flux is being calculated through the clay, so the effective porosity should be lower than 25 percent. Table 2-22 appears to be using .110 for effective porosity, so please revise the text to agree to what is shown in the table. Also, please note that there is a typo error in the spelling of conductivity in the table. Also, please reference where the hydraulic conductivity value of clay originated.	C/E	The comments have been addressed by revised text. The sentence reading "*An effective porosity of 25% of the total porosity was assumed.*" Has been replaced with "An effective porosity of 11% is 25% of the reported total porosity of of 44% for the clay. The reference to 25% and the effective porosity of 11% in Table 2-22 have been provided in a footnote. In fact, 11% effective porosity was assumed for the calculation of mass flux through the clay layer. The typo for conductivity in Table 2-22 has been corrected. The reference for the hydraulic conductivity value for the clay is from a soil sample from 18CPTMW01 from a depth of 40 – 40.5 feet bgs. Table 2-22 has been revised to move the reference from the column label to a footnote at the bottom of Table 2-22.	A
34	Page 2-25	Section 2.4.4, General Comment	This section has several inconsistencies between the tables and text. EPA found the section to be confusing, therefore, EPA would like to have a technical discussion with the Army and their contractor to clarify certain sections. EPA did include a few comments found below, but feels it would be better to discuss the section face to face than to write multiple comments and questions. EPA does recognize the efforts to use the new data to further characterize the vertical component at the site.	C	A call was scheduled at a mutually agreeable time to have a real-time discussion of this section. Prior to that call, the text and tables were reviewed for inconsistencies, which were identified during the discussion.	A

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
35	Page 2-25	Table at the Bottom of Page	The concentrations of TCE, MC, and perchlorate in MW-2 from June 2016 concentrations do not match with the values shown on the isopleth figures. Therefore, the ratio calculation is not correct. The values should be 15.5, 21.3, and .033. Please check the maximum values, since the perchlorate value shown in the table for MW-2 shows 32.2 ug/l in October 2000 and figure 2-5 shows 40 ug/l for perchlorate in April 2001. The concentrations for MW-7 agree with the June 2016 maps. In addition, EPA would like to have a brief technical discussion with the Army and their consultants to discuss the vertical mass flux determination. In some places the text is not clearly understood.	E/C	Please note that the values in the table at the bottom of page 2-25 are in mg/L, not µg/L as indicated in the third sentence of the comment. However, the maximum perchlorate concentration should be 40 mg/L (April 2001) and has been corrected in the table. The table has also been revised to reflect the reported concentrations for MC, TCE and perchlorate in MW-2 as 21.3 mg/L, 15.5 mg/L, and 0.033 mg/L, respectively. Based on this revision, the calculated ratios for MC, TCE and perchlorate were revised to 1,254, 98.1, and 1,212, respectively. The revised ratios still reflect a 2 to 3 orders of magnitude decrease in concentrations from maximum values and therefore the conclusions discussed on the following page (2-26) are still valid.	A
36	Page 2-26	First Paragraph	The first sentence is confusing. *"As can be seen from the data for monitoring wells MW-2 and MW-7, the ratio of COC between the maximum reported concentrations and the most recent concentrations ranges in MW-2 ranges between 7.1 and 322,000."* Please rewrite as follows: "As can be seen from perchlorate data for monitoring wells MW-2 and MW-7, the ratio of perchlorate between the maximum reported concentrations and the most recent concentrations ranges between 7.1 and 322,000. Please note that he 322,000 value will most likely change based on the previous comment.	C	The referenced sentence has been re-written as indicated except the maximum ratio value is changed to 1,212 (see response to previous comment).	A
37	Page 2-29	Minor Editorial Comment, Last Sentence	EPA recommends changing the end of sentence from "*be evaluated in the Revised FS*" to "be evaluated in this FS".	C	Assume this comment refers to the last sentence of the third paragraph on page 2-29. The suggested change has been made.	A
38	Page 3-1	Last Paragraph	This is the first use of NCP in text. Please define.	C	The definition of NCP – National Oil and Hazardous Substances Pollution Contingency Plan – has been added.	A

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
39	Page 3-4	Section 3.2.2.2	This is the first use of SDWA in text. Please define.	D	The first use of SDWA is on page 2-2, where it is defined as the Safe Drinking Water Act.	A
40	Page 4-2	First Bullet, Last Sentence	EPA has made this same comment on the draft FS and PSI documents. EPA agrees that the recent additional work has greatly improved the understanding of the hydrogeology and plume delineation. However, there are still some locations at the site where the groundwater concentrations are above the MCL (at Wilcox wells which do not have deeper screened wells in the vicinity, i.e., MW-14), thus the vertical extent of the contamination is not known. EPA has agreed that these additional deeper wells can be installed during the RD.	--	Noted. The last sentence was changed to indicate that the "lateral" extent of contamination in the Wilcox Formation is known, however determination of the maximum vertical extent of contamination may require installation of additional deeper Wilcox wells during the design phase".	A
41	Page 4-3	Second to last Paragraph	Please add "shallow' in front of "groundwater (118,000 µg/L …), since higher concentrations have been found in the Wilcox.	C	The word "shallow" has been added before "groundwater".	A
42	Page 4-20	Last Paragraph	The first use of ASTM, please define.	C	The definition of ASTM – American Society for Testing and Materials – has been added.	A
43	Page-4-27	General Comment	Please include the other options for effluent water discharge or storage (i.e., larger tank to hold water until it can be released to bayou). EPA would prefer that no effluent water be disposed of onsite by irrigation or injection.	E	Since all of the potential remedial alternatives were screened with the same assumption of effluent handling, revising the handling of effluent would not result in any substantive change in the comparison of alternatives. Therefore, this issue is more appropriate to address in the remedial design phase. Also, as indicated in the response to comment 26, in Section 4.4.1.7.3 – Reinjection, the sentence before the first bullet has been replaced with the following: "However, reinjection of treated wastewater has not been performed at the GWTP since 2012 and resumption of the practice is unlikely due to potentially deleterious risks."	A

1	General	Since the Draft PSI Addendum Report and the Draft FS are being submitted concurrently and being reviewed by EPA for the first time, the Army needs to ensure that these two documents are synchronized. Under CERCLA process, the Draft PSI Addendum should be submitted before the FS. Secondly, environmental information from the complete PSI investigation, including data from monitoring wells 18CPTMW22SW, 18CRT03MWSW and 18MW24, must be fully addressed in the both the FS and in Appendix B, Draft PSI (currently neither document contain this complete information). This includes all affected tables, figures and text or any other pertinent sections which would be applicable to either document. This will require the current documents to be revised. In addition, from the review of the Draft PSI Addendum, EPA recognizes the presence of substantial contamination in the shallow Wilcox within and outside the southwest quadrant of the containment area.		The PSI report was finalized before the FS. Information from newly installed wells was included in the PSI report and the FS report. Investigation of the southwest quadrant has been conducted in March/April 2016 and the results included in a standalone investigation report and in the FS.	A				
2	General	EPA does not support deferral of unsaturated soil cleanup to some unknown future date. Although groundwater concentrations may be higher than overlying soil concentrations today, if proposed groundwater and source area remedies are successful, these source soils will eventually require appropriate management to mitigate groundwater risk. Over the timeframes contemplated, EPA believes it will be too easy for future project managers to overlook these subtle nuances and these source soils may never be addressed. Alternatively, the Feasibility Study and all subsequent documents (PP, ROD, RD, RAWP, FYR's, etc.) must make specific reference to future requirements to remediate these source soils. If deferred, the FS cost estimates should be revised to include the full costs to remediate and manage these soils.	C	The cost of remediation for the two areas beneath the UEP will be developed and included in the FS. The cost estimate will assume the remedial action, if implemented, would not occur until 2024 at the earliest, or approximately 5 years after commencing treatment. Currently, all FS alternatives include UEP cap maintenance to prevent infiltration of rainwater. Hence, the FS and all subsequent documents (PP, ROD, RD, RAWP, FYRs, etc.) will make specific reference to the future evaluation of removal of the soil under the cap.	A	Agree; however, EPA still does not understand the time delay. Is the UEP subsurface soils less of a priority versus other subsurface soils at the site? Or is the remedy based on some threshold?		The third from the last sentence of Section 5.2.2 on page 5-5 of the Revised FS has been replaced with: "Removal of contaminated soil under the UEP may be performed as a contingent remedy in the future, if conditions change such that it poses an imminent threat to human health or the environment. Currently however, the existing cap effectively prevents human contact with contaminated soil, and minimizes infiltration of precipitation/runoff that could potentially mobilize COCs in the waste and impact shallow groundwater. The cap is regularly maintained and inspected to ensure its continuing effectiveness. If in the future, groundwater monitoring detects a significant increase in COC concentrations in wells downgradient of the UEP, and/or the water table elevation rises significantly, causing a large part of the underlying waste to become saturated, a detailed evaluation would be performed to assess the need for a contingent remedy, either for the soil or for the groundwater. The RD will address the triggering criteria for evaluating whether a contingent remedy is needed."	A

3	General	The current remedial system has not been optimized. Pages 2-16 of the FS (AECOM, 2015) indicates that downward head gradients occur under contaminated zones of the shallow aquifer. Additional vertical extraction wells may be needed to ensure upward flow occurs. Reactivation of several interceptor drains may also be warranted. Recharge into interceptor trenches or sprinkled lawn irrigation should not be done. Recharge of treated water near MW-1 produces mounding and facilitates downward flow into the Wilcox formation.	E	The current remedial system is running at optimum capacity. Each ICT has its own design capture zone that changes with the groundwater level and recharge rate at the site. Those capture zones cannot be optimized as they are influenced by system design, groundwater formation limitations, and groundwater elevation. Comparing shallow zone groundwater levels to the Wilcox aquifer groundwater levels from June 2014 results reveals the following well pair heads in ft amsl: MW-2 (168.73) vs. 18CPTMW01SW (168.75); MW-5 (168.87) vs. 18CPTMW08SW (168.77); MW-21 (166.48) vs. 18CPTMW07SW (168.75); MW-22 (169.64) vs. 18CPTM06SW (168.52); 18CPTMW04 (171.41) vs. 18CPTMW04SW (168.75); MW-7 (168.54) vs. 18CPTMW12SW (168.75); MW-9 (169.42) vs. 18CPTMWSW10 (168.98); 120 (172.24) vs. MW-14 (172.33); C-02 (169.50) vs. MW-13 (169.31); 18WW08 (169.07) vs. 169.04). With the exception of MW-22/18CPTMW06SW and 18CPTMW04/18CPTMW04SW, the head differences are either flat or pointing upward (examples: MW-21/18CPTMW07SW; MW-7/18CPTMW12SW; 120/MW-14). Therefore, the general statement that the heads in the impacted zones are downward does not fully represent extraction conditions. Areas MW-22 and 18CPTMW04 are the areas adjacent to and influenced by ICT9 and ICT6, respectively. As indicated during development of the conceptual site model, reinjection of treated water was deemed to be a poor practice and was discontinued. Irrigation has been occurring on the western portion of the site and the downward heads identified at the two locations above are observed on the eastern portion of the site. These areas are not influenced by irrigation water. No current recharge near MW-1 is taking place and the lack of a Wilcox well at that location precludes concluding that mounding is present there that facilitates downward flow into the Wilcox Formation. Additionally, natural mounding near 123/AWD-2 has been identified in 1992 maps, which supports that current irrigation is not causing the discussed mounding at the site. A third irrigation line has been added in January 2016 to provide a better distribution of irrigation water around the site.	A/D	EPA appreciates the additional vertical gradient analysis provided in the report. The mound observed in 1992 is most likely the remnants of the UEP. The current mounding in the shallow zone is further to the west and appears to happen in areas where there has been a history of ICT pump failures. Current maps (figure 1-7) show mounding in the northwest corner in the vicinity of MW-14 in the Wilcox. EPA agrees that there appears to be an upward head at wells MW-14/120; however, EPA has witnessed on several occasions that the area is over irrigated and the USGS geophysics (study of October 2015) indicates close to total saturation in the northwestern corner of the site which emanates outwards to Harrison Bayou, thus EPA does not concur with irrigation on the site and would prefer the release of treated effluent to the Bayou. In regards to the comment about MW-1, the report states on page 2-18 that there is a downward gradient at MW-1, probably due to the influence of injected water in the area. There are areas of downward gradient in the containment area and outside the area, so in those cases remediation should minimize or redirect the gradient. The new FS does indicate turning on two of the ICTs, so in those cases wells in those areas should show an upward gradient. In addition, until recently, there were very few wells completed in the Wilcox that could be used to determine vertical gradient, so prior to injection and irrigation, the gradients were not known.	D	Although the Army understands EPA has concerns about the use of irrigation with treated wastewater at the site, the Army does not agree that irrigation should be discontinued. Discharge to Harrison Bayou is the preferred method for treated wastewater disposition. Irrigation or temporary storage in the INF Pond is performed only when the preferred method of discharge to Harrison Bayou is precluded by inadequate or no flow in Harrison Bayou. Noted.	A

4	General	The potentiometric head contours and the isopleths for COC concentrations both show a large amount of closed contours-particularly low heads. A hydrogeologic reason needs to exist for the low head to occur. Reasons include extraction, high permeability zones, downward flow zones, etc. Please check to see that the water level data was measured at the same time. Furthermore, the use of long screen wells may complicate the contouring because vertical flow exists and data represents different hydrogeologic units.	C	Noted. The water level at site 18/24 is typically measured within the same day with occasional situations where measurements could occur over two consecutive days. The use of closed contours is an artifact of the contouring program. Attempts to manage areas of closed contours have been implemented.	A				
5	General	It may be helpful if both hydraulic and chemical budgets are constructed for the site. Hydraulic budgets include information on the components of extracted water at the site. For the shallow aquifer, extracted water should equal= recharge+ lateral inflow to containment area + vertical upward flow. The amount of vertical upward flow is important to ensure a reduction in COC transport in the Wilcox Formation. Areas lacking the Wilcox clay should be identified and the rates of vertical transport estimated.	E	Noted – please also see the response to Comment 3. The analytical and head data currently collected are considered sufficient to characterize potential vertical transport for the current phase (FS) and to identify areas where it should be considered during the remedial design process.	A	Please see new comment 32 which pertains to the original comment and how it may have been addressed.			
6	General	A key decision on conceptualization of perchlorate at the site comes from observations of well concentrations at well 120 (p. 2-17). They indicate that the perchlorate resides in pore spaces and not as separate brine based on concentration ranges at the well. The reliability of the sampling and concentration data to reflect in situ groundwater concentrations (representing a good sample) should be high to support critical decisions. A recent EPA analysis of purge data (EPA can provide this analysis) shows that sufficient uncertainty exists on reproducibility of sampling at the site that suggests additional sampling methods may need be incorporated into the monitoring. The results of the purge analysis indicate that samples are being collected without adequate purging and the samples reflect casing water to a large degree and not fresh groundwater entering through the screen from the aquifer. Further, the sample does not integrate the potential variation of chemistry for the entire screen length, just a small part. Vertical profiling with passive samplers would help delineate the variation of COC concentration for the entire screen, after which, individual samples can be collected from the appropriate depths.	E	The majority of the wells are sampled using a low flow method, which is an accepted EPA and TCEQ methodology and is the primary method for monitoring well sampling specified in the IWWP (AECOM, July 2014). The low flow method requires wells to be purged at a low flow rate until stabilization of a specified set of water quality parameters within specified limits is achieved and representative groundwater samples can be collected. The final purge water parameters reflect the adequacy of groundwater purging. Monitoring well 120 had a perchlorate concentration of 122,000 ug/L, which is not at the level that would cause stratification. Monitoring well 120 is screened within a mostly sandy zone with little heterogeneity, so retardation or trapping of high concentrations of perchlorate in pockets is unlikely. Changes in perchlorate concentrations are typically observed over time and affected by seasonal variations. Remedial efforts targeting an area like 120 will consider worst case scenario with a factor of safety applied to the remedial design. That said, groundwater samples were collected from several wells from near the bottom of the screen (bottom samples) and from near the top of the screen (top samples). The results from these samples were shared with EPA. None of the results indicated the occurrence of stratification or inadequacy of purging.	D	EPA would agree that micro-purging is normally an acceptable technique at most sites, but the EPA study did show stratification in at least one well (MW-14) as did the Army's own sampling at the top and bottom of the screen. Based on the EPA/USGS study (October 2015), it indicated that there can be a significant difference in concentrations based on purged volume (high and low). In addition, the ICTs tend to show higher concentrations of COCs than the nearby wells, further indicating a heterogeneous system and is difficult to monitor by traditional well sampling. As an example of heterogeneity, MW-16 had a concentration of perchlorate in June 2015 of 9370 ug/l, but in June of 2016 the perchlorate concentration was 0.615 ug/l.	D	Our knowledge of the site is sufficient for remedy selection. Design and compliance monitoring details will be addressed in the remedial design and implementation phases, after the remedy is selected.	A

7	General	Velocity and transport of COCs are not included in the FS; a surprising lack of hydraulic property information exists. COC transport rates should be included to help facilitate selection of remedy. EPA has recently completed an analysis and would be willing to provide this with the Army.	C/E	Thank you for sharing the analysis. The information may prove useful during the remedial design phase. During remedy design, transport of injected substrate over its design life span will be calculated to determine the travel length the substrate will cover. However, this will be done at the localized injection locations but not for the entire site.	A				
8	General	Table 2-13 appears to be a critical element in assigning predicted remediation times. It is unclear how Table 2-13 was created. Based on Table 2-13, remediation timeframes for alternatives presented ranged from 5 to 500 years. Additional information (see later comments) is needed to substantiate predicted timeframes.	E	Table 2-13 is determined from the total mass of each contaminant in the shallow groundwater zone and on the existing system extraction rate, assuming no attenuation of contaminants due to sorption or due to the presence of DNAPL. Tables 2-10, 2-11, and 2-12 and Figures 2-6 and 2-7 provide contaminant flux calculations and Tables 2-4 through 2-8 provide contaminant mass calculations in the shallow zone. The overall mass of a contaminant in the groundwater zone divided by the estimated extraction flux provides the average timeframe to achieve the endpoint.	A				
9	General	Proposed remedial scenarios that include injection may have unforeseen consequences such as mobilization of DNAPL to unknown locations if injections are not carefully planned. Downward movement of DNAPL to the Wilcox Formation is a concern. Technologies such as ERT heating can reduce the risk of injections.	E	Chlorinated VOC DNAPL is by nature heavier than water and has the potential to desiccate clay and migrate vertically downward. This has not occurred to date although COCs have been observed in the upper Wilcox Formation. Additionally, injection of fluids will be on a very short term basis and in limited areas of the site and not across the site, limiting the concerns about the vertical migration potential. Use of surfactants to mobilize DNAPL has its risks; however, the technology is associated with extraction of mobilized fluids at a rate that should minimize or prevent downward migration of DNAPL. Additionally, surfactants that solubilize DNAPL results in a solubilized form of DNAPL contaminants thus removing the concerns of downward movement of DNAPL to the Wilcox aquifer. That said, DNAPL mobilization during remedy assessment will be added to the risk factors.	A				
10	General	Several checks on Table 2-5, used to determine mass of COCs, disagree with what is reported. Table 2-5 should be revised to incorporate thickness and porosity in a separate column in order to follow computations more clearly. The amount of sorbed mass, included in Table 2-6, suggest that the sorbed mass for MC is equal to the dissolved whereas TCE sorbed mass is twice as much. Both sorbed calculations should be included in their entirety in	E	The porosity and thickness used in calculations in Table 2-5 are presented at the bottom of the table. An equation is introduced at the bottom of the table to provide the parameters and conversion factors used in calculating the dissolved phase mass. The observation made about soluble mass to sorbed mass ratios is correct. MC is more soluble than TCE and therefore with lower Koc, the ratio of soluble to sorbed mass for MC is higher than TCE. An equation for estimating sorbed mass on soil from	A

<table>
<tr><th>Comment #</th><th>Section/Page Reference</th><th>Comment</th><th>C, D, E or X[1]</th><th>Response</th><th>A or D[2]</th><th>Comment</th><th>C, D, E or X[1]</th><th>Response</th><th>A or D[2]</th></tr>
<tr><td></td><td></td><td>Table 2-6 to verify values.

Capture efficiency for the remedial system is COC dependent. The below table provides data to illustrate this point. Capture efficiency is defined as the ratio of mass flux captured to dissolved mass. Perchlorate capture is poor relative to other COCs. Why? Is it related to the capture area and plume distribution or is it a mobility issue? The fact that MC capture is almost 1:1 with the estimate of the dissolved plume mass for MC indicates that either a separate source exists for MC or the dissolved plume is underestimated.
<table>
<tr><th>Dissolved mass (Table 2-5)</th><th>COC</th><th>Mass Flux (Table 2-12, year 2014)</th><th>Annual Efficiency of capture (Mass/Diss)</th></tr>
<tr><td>12,514</td><td>Perchlorate</td><td>1,670</td><td>.13</td></tr>
<tr><td>1,181</td><td>MC</td><td>1,260</td><td>.93</td></tr>
<tr><td>651</td><td>TCE</td><td>1,393</td><td>.47</td></tr>
</table></td><td></td><td>dissolved concentrations is added to the footnote of Table 2-6.

The values shown in the table of the comment have been misplaced. The table below shows this information with corrected location of the numbers. However, the annual efficiency seems to have been correctly determined.
<table>
<tr><th>Dissolved mass (Table 2-5)</th><th>COC</th><th>Mass Flux (Table 2-12, year 2014)</th><th>Annual Efficiency of capture (Mass/Diss)</th></tr>
<tr><td>12,514</td><td>Perchlorate</td><td>1,670</td><td>.13</td></tr>
<tr><td>1,260</td><td>MC</td><td>1,181</td><td>.94</td></tr>
<tr><td>1,393</td><td>TCE</td><td>651</td><td>.47</td></tr>
</table>
The mass flux determination was based on the concentration in the extraction point and the flow rates. Since concentrations are measured only once a year, an approximation was made by assuming that the measured concentration is representative of the entire year. This is why two years of flux calculations were used to minimize dependence on a single measurement for flux calculations. The determined mass fluxes for these chemicals reflect their distribution at the site, the concentrations in each extraction point, and their physical/chemical characteristics. For example, perchlorate is present in a larger area of the site and has higher solubility than the other two chemicals which is reflected in a higher flux rate. MC is more soluble than TCE and shows a higher flux rate. The table shown in the comment only reflects the dissolved mass estimate and neglects sorbed mass and mass in DNAPL for MC/TCE. Therefore, the simple analysis to calculate capture efficiency is not a complete representation of site conditions. For MC and TCE the sources contributing to the dissolved plume are the sorbed mass and the mass within the DNAPL.</td><td></td><td></td><td></td><td></td><td></td></tr>
<tr><td>11</td><td>Page x</td><td>Please add the references for reports discussed in the first couple of sentences on top of this page.</td><td>C</td><td>The three references are all included in Jacobs Engineering Corporation’s reference, 2001. This information is added to clarify this point. The Jacobs’ report is included in the references section.</td><td>D</td><td>It is common practice in technical reports to include all references listed in a report. Yes, these references may be in the Jacobs report, but a reader should not have to go to another report to find the references listed in the report they are reading.</td><td>C</td><td>In the Revised FS, all documents used to develop the FS are included in the References section. However, some of the items included Table 1-1 are not actually documents, i.e., bulleted items describing activities included in primary reference documents, or are secondary references that were not consulted. It is not appropriate to include these in the references section.</td><td>A</td></tr>

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
12	Page xi, 2nd Paragraph	Please define GW-ind.	E	The reference to GW-Ind is no longer valid. The document has been revised to replace references to GW-Ind with the TRRP PCL as the cleanup level for all non-MCL groundwater constituents. Definition of TRRP PCL added in text.	D	GW-Ind is still located in report and should be defined. Please see page xiii, 2nd paragraph.	C	GW-Ind is defined in the Acronyms and Abbreviations and where it first occurs on page xiii.	A
13	Page xi, First Bullet	First use of VOC, please define in text.	C	Definition added in text.	A				
14	Page xii, Alternative 3	Please define MNA (first use).	C	Definition added in text.	A				
15	Page xiii	First use of DNAPL and ZVI. Please define both in text.	C	Definition added in text. Definition for DNAPL and ZVI is found on Page xi and xiv, respectively.	A				
16	Page xi, 2nd Paragraph	EPA believes that COCs without MCLs must meet the TCEQ TRRP residential PCLs for groundwater. See the Administrators decision of October 31, 2014.	C	Please refer to the response to Comment #12.	A	Please see response to comment 12.			
17	Page xi, Groundwater RAOs	More specificity is needed in the cleanup numbers such as EPA MCLs, TRRP PCLs for contaminants without MCLs for the surface water and groundwater exposure routes.	C	Please refer to the response to Comment #12.	A	The wording is now found on page xiii.			
18	Page xii. Alternative 3	Please state how deep the slurry wall will be installed. Will a cap be used with the slurry wall?	C	Added text to provide depth of slurry wall. More details are presented in Section 5 with information detailing depth of wall at various locations around the site (see Figure 5-3). The information provides that a partial cap will be installed.	A				
19	Page 1-4, Fourth Paragraph	"*The treated water is primarily released to Harrison Bayou. Occasionally, the treated water is released to Harrison Bayou*". Are these statements accurate? It would appear to EPA that in the past few years much of the water has been re-injected or irrigated at the site, which is more of the normal occurrence than release to Bayou. Do you have the total volumes to support this statement?	C	Modified statement to indicate that the intent is to discharge primarily to Harrison Bayou with other release forms to be secondary mechanisms.	A				
20	Page 1-5, First Paragraph	The first sentence refers to Figure 1-4 that illustrates all the data collection points prior to the PSI. However, the text describes some data collected as part of the PSI (i.e., deeper monitor wells). EPA suggests adding the following statement to end of first sentence "prior to the PSI investigation".	C	The statement is added to the first sentence.	A				
21	Page 1-5, Third Paragraph	"*Localized influence of groundwater extraction can be observed in the shallow aquifer*". Please also include a statement that the influence of irrigation and problems with pumps in ICT 13 also influence	D	Mounding near ICT13 is a historical norm prior to operation of the extraction system or application of irrigation water based on information presented in Figure 1-8 where the northwestern area of the site	D	The mound shown in the 1992 figure resides near the UEP which would be expected since it was unlined. The mound has moved towards the west since installation of the IRA and now there appears	D	Please see 2004 groundwater levels for monitoring wells 123 and MW-14 presented in contour maps in Appendix III of the attached document: "Longhorn Army Ammunition Plant Groundwater Treatment	A

		groundwater contours (mounding). EPA has observed that irrigation runoff normally flows towards the area in the northwest corner. EPA has also observed that mounding occurs along ICT 13, since a pump has not been working in that portion of the ICT.		shows higher groundwater levels. Additionally, regardless of whether ICT13 pumps are all functioning at peak capacity or any pump is malfunctioning, the mound remains persistent. For example, all six ICTs were functional (with the exception of ICT 13G which has not been operational for many years) and extracted approximately 185,000 gallons in January 2015; 291,000 in February 2015; and 222,000 gallons in March 2015; however, the water mound around monitoring well 123 persisted. Note also that the groundwater extraction system is an interim remedial measure and does not represent a final solution.		to be mounding in the Wilcox at MW-14 and EPA believes that is a reflection of constant recharge from irrigation. EPA agrees the mound seems to be continuous around monitoring well 123, but there is still constant recharge in that area from irrigation. EPA believes that the mound may dissipate if irrigation is discontinued. 12/12/16 Follow-on comment: "After careful review of the 2004 Report, EPA agrees that the ground water levels for the monitoring wells (MW-14 and 123) look very close or similar to the most recent levels taken in 2015/2016. However, EPA has observed that the contaminant levels of MW-14 and MW-16 (northwest corner of site) have increased rather dramatically since 2004. In 2004, MW-16 had no detections of perchlorate and TCE. The results for MW-16 from December 2015 indicate TCE at 433 ug/L and perchlorate at 1060 ug/L. For MW-14 in 2004, TCE was 224 ug/L, MC was ND and perchlorate was 2,190 ug/L. The results for MW-14 from December 2015 indicate TCE at 15,500 ug/L, MC at 54.7 ug/L, and perchlorate at 285,000ug/L. These wells are located in area (or close nearby) where EPA has observed excessive irrigation and runoff from the site the past 3-5 years. EPA believes that the excessive sprinkling is most likely leaching/pushing contaminants downward and outward in this region of the site. For future actions at Site 18/24, irrigation will have to be better controlled and managed for EPA approval of this practice."		Plant Annual Evaluation Report, Calendar Year 2004, Longhorn Army Ammunition Plant Site 18/24 and Site 16" (Complete Environmental Service, February 2005). These figures document the presence of historical mounding in this part of the site before the practice of irrigation began. Noted.	
22	Page 1-5, Last Paragraph	This section describes water supply wells in the area. EPA believes that there are other wells used by the public in the area, particularly one numbered 3524402 located to the northeast of LHAAP 18/24.	C	A new water well search was conducted and the information has been updated.	A				
23	Page 1-5, Figure 1-6	EPA interprets the contour map to indicate more of a complex flow pattern rather than a radial flow pattern.	C	The flow pattern depicted on Figure 1-6 is rather complex and is influenced by multiple water drainage areas and the groundwater extraction system. Groundwater flow is outward from the containment area in all directions, based on the groundwater surface contours. The text on page 1-5 has been revised to add the description "complex" to the term radial flow.	A	Please see EPA comments on PSI about the use of 18CPTMW22R for contouring.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
24	Table 1-1	All reports listed in this table should be included in reference list at end of this report.	C	Please be specific on which references are not included. As indicated in response to comment 11 above, the four references in Table 1-1 under Jacobs 2001 are included in the report which is provided in the reference list.	D	It is common practice in technical reports to include all references listed in a report. Yes, these references maybe in the Jacobs report, but a reader should not have to go to another report to find references listed in other reports. In addition, the USEHA, 1980 reference in the table may be confused with another USEHA, 1980 that is referenced in this report. However, these are two different reports. The comment asked for ones missing from the reference, which would be USEHA, 1980; EPS, 1982; CDM, 1986; and EPA, 1987.	C	Please see response to comment 11. Also please see responses to EPA comments 3, 6, 7, 9, 13, 15, 21, and 50 on the Draft Final LHAAP-18/24 Revised FS.	A
25	Figure 1-3	Is there an extraction well(s) missing on the Figure? EPA recommends including color coded extraction rates. In other words, showing a map with contours next to the ICTs average or monthly extraction rates.	D	There are no known extraction wells missing. The intent of the figure is to show the layout of the site and the locations of former storage, disposal and treatment areas. .	A				
26	Figure 1-5	This Figure presents a three-dimension rendering of the Wilcox clay surface. Please also present an isopach map of the Wilcox clay to complement Figure 1-5. The isopach map will allow easier identification of thinner clays more easily breached by vertical contamination migration and will facilitate comparison with monitoring wells installed into the Wilcox formation.	D	The thickness of clay is known only in a limited number of locations where Wilcox wells/borings were installed, particularly inside the containment. Therefore, a true isopach map will be lacking important details, and an interpolation of Wilcox clay thickness could present misleading information.	A	However, the point should be taken that the thickness of the clay is important in regards to contaminant migration both laterally and vertically.			
27	Figure 1-7	There is no justification for the enclosed contours (no monitoring wells to the west) by well 18CPTMW12SW.	C	The cause of the contour line closure to the west of 18CPTMW12SW is related to groundwater elevation at 18WW15 to the southwest of 18CPTMW12SW which has a very similar elevation (168.59 ft amsl at 18WW15 and 168.75 ft amsl at 18CPTMW12SW). This caused the 168 ft amsl equipotential line to wrap around. However, the 167 ft amsl contour line should not be closed. The potentiometric maps have been updated to eliminate closed contours that are not justified by the data.	A	The original comment is no longer valid since the data for this map is from June 2016 and the newer data has been contoured.			
28	Figure 1-8	This figure is hard to read. EPA recommends using the revised figure 4 (somewhat easier to read) that is to scale from the USGS report entitled "Evaluation of Interim Remedial Action at Longhorn Army Ammunition Plant site 18/24, Karnack, Texas, 2012".	E	Although figure 4 may be easier to read, Army prefers the figure taken directly from the original document. The figure is a scanned map from a 1994 report. Army plans to replace the 1994 map with a map from 1992. The quality of the 1992 map is such that the contour lines and monitoring wells are clearly identified.	A	The new map from 1992 had not been seen before by EPA. It is easier to read than the 1994 map.			
29	Figure 1-2	This figure should also include the non-drinking water wells.	C	A new water well survey was conducted and the map updated.	A

2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
30	Figure 1-4	While the figure is very informative, there should be individual figures provided per the media sampled.	D	This figure is added for informational purposes only to provide a representation of historical work. It was not meant to provide a detailed account of historical events.	A				
31	Figure 1-5 of Appendix B	There are four circular low potentiometric contours drawn on the map. Circular lows can only occur if they are discharge areas to wells, trenches, or evapotranspiration areas, or, there is significant vertical flow at the site.	X	This comment is related to the PSI Addendum which has been finalized.	A	The reviewer agrees that this comment is on the PSI, but one thing to note is that the gradient in the western area of the Wilcox appears to be coming from the bayou towards Longhorn Site 17 (from the map in the most recent PSI, March 2016, figure 1-5). The updated map in the FS from June 2016 (figure 1-7) data does not indicate the same feature. Well 18WW11 water level in June 2016 has decreased by almost 3 feet since the March reading. This is quite a dramatic change over a few months. EPA believes this may be due to the localized flooding which may have temporary reversed gradients within the Harrison Bayou Floodplain.		Noted.	A
32	Figure 1-10	Contours should not be enclosed between MW-14 and 18WW11 and 18WW02 because no data is shown.	C/E	The contours are closed based on data from recent sampling events indicating concentration in 18WW02 and 18WW11 below the MCL. For example, the concentration in 18WW11 was < 0.20 µg/L in December 2013. 18WW02 was reported at 0.216 µg/L in December 2014. Note the figures in the FS will be updated to include at a minimum data from December 2014 or more recent.	D	Figure 1-10 in FS does not include a concentration for well 18WW11. In addition, if the data from well 18WW02 is from December 2014, it should be flagged with a comment in the legend.	E	Figure 1-10 in the Revised FS was generated using perchlorate concentrations detected in samples from June 2016. Although 18WW11 was not sampled (no concentration is shown for this well symbol), the perchlorate concentration in the June 2016 sample from 18WW02 is <0.2U. Therefore, the closed contours are justified.	A
33	Figures 1-9 thru 14	Please ensure that all the monitoring wells installed during full PSI are included. It appears that a few are missing. Also, please include only the wells on the figure used to make isopleths. This comment also applies to all figures that show wells that are not used being for plume delineation or water level contouring.	C/D	The maps have been updated with more recent data which include all the wells. Army prefers that all the wells are included and labeled for completeness.	A				
34	Figure 1-12	The wells on this map are designated as shallow Wilcox and deep Wilcox. It appears that this map only shows shallow Wilcox data. There were some detections of VOCs in the deeper Wilcox. Please show these results on this map for the deeper Wilcox.	D	Results are shown for the wells that were sampled. No data indicates the well was not sampled.	D	For this map, it appears that only two DW wells were sampled and the remaining wells were not sampled, so the comment stands that this map is for the shallow Wilcox aquifer. EPA will expect sampling of deeper wells in the future for LTM. EPA believes that 18CPTMW08DW (perchlorate at 682 ug/l) has had several past detections above the MCL. Also, in the location of well MW-14, the vertical extent of contamination has not been determined and will need to be addressed in the future too.		Noted.	A
35	Figures 1-15 & 1-16	Please provide the MSC number in note no. 4.	E	Please see the response to Comment #12.	A

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
36	Figure 1-17	While the Figure is very informative, there should be individual Figures provided per the media or the item to be illustrated to reduce the "clutter effect" on a reviewer.	D	This figure is added for informational purposes only to provide a representation of historical work.	A				
37	Figure 1-18	EPA understands that this Figure excludes locations sourced from groundwater. From the text, the EPA assumes this means those samples within the smear zone, as defined by historically high water levels. As indicated in comments on Appendix B, EPA is not presently able to support exclusion of soils based on these criteria. Additional information may facilitate EPA acceptance of Army's proposals for excluding these soils. It is not clear if this Figure also excludes locations where the Army indicates that groundwater contamination levels are currently higher than overlying unsaturated soils concentrations even if those soil concentrations exceed groundwater protection criteria. Please clarify. This Figure may require adjustment pending outcome of additional clarifications.	D/C	The smear soil zone is part of the groundwater fluctuation zone and is considered within the groundwater aquifer and cannot be considered vadose zone soil. The impacted smear zone soil could become a secondary source of contamination to groundwater. However, if in-situ remediation of groundwater is done in a manner to leave residual substrate in groundwater or conducted under high water conditions (example when the extraction system is turned off during ISCR) then the smear zone soil will be cleaned up simultaneously with groundwater. The figure shows all points where vadose soil impacts exceeds groundwater protection standard regardless of whether the soil has higher concentrations at this time (e.g., locations 8A-975, 8A-911, and 18SB02 had higher groundwater concentration for TCE than in the soil but they are included in the remediation scope of work for unsaturated soil). Similarly, vadose zone soil concentrations under the UEP are included in this figure and will be included in the remedial design as areas of potential source of contaminants.	A				
38	Page 1-8, Area West of ACD	Based on previous soil investigations, it does not appear that there were perchlorate soil samples taken in the area of 18CPTMW22. This well detected over 100k ug/l of perchlorate. What is the source of the perchlorate in this well? How does the Army justify that there is not a soil source in this area? It appears additional soil samples need to be collected in this area to demonstrate that soil is a source or not.	C	Clarification is requested. The area west of the ACD is the area where 18CPT27 and 18CPT09 are located. Soil samples for perchlorate were collected from these samples. 18CPTMW22 is located to the south of the site and is not associated with the ACD. Evaluation of soil data in and around 18CPTMW22 was conducted and the results compiled in a standalone Supplemental PSI report which is appended to the revised FS.	A				
39	Table 1-1	The details provided for the PSI beginning in 2013 seems rather sparse compared to the amount of work performed.	D	The entire PSI Addendum report has been submitted and approved as a standalone report. The reviewer is encouraged to seek the details desired from that report.	D	More detail should be added to the additional investigations, similar to the summaries of the other reports. In the future, readers could then determine what was done for each main study instead of looking through previous reports.	D	No additional information will be added to the table. Section 1.1 of the Revised FS now includes references to the two stand-alone post-screening investigation (PSI) reports – the Updated PSI Report (AECOM, 2016a), and Supplemental to the Updated PSI Report (AECOM, 2016b). These reports provide the most recent and comprehensive information on the site since the RI (Jacobs, 2001).	A

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
40	Table 1-2	EPA suggests adding a sentence to the end of this table. For example, "*Injection of treated water into ICTs was discontinued in 2012. Irrigation of treated water on the site has continued when there is not enough flow in Harrison Bayou for the release of treated water.*"	C	Statements added.	A				
41	Table 1-3	The notes on the bottom are confusing. Are there stand pipes used for TOC measurements? Also, TOC is defined twice with two different definitions. Please clarify.	E/C	Yes, there are standpipes where the pumps are. These are as built measurements. Second definition for TOC deleted.	A				
42	Figures 2-3 & 2-4	Please provide larger maps or use maps provided in the EPA/TVA/USGS IRA report.	D	These figures are from the original report and are sufficient for the intended purpose.	A	The new 1992 maps vs. the 1994 are much better.			
43	Tables 2-1, 2-2 & 2-3	Please include 1,4 dioxane in these Tables.	C	1,4-dioxane has been added to Tables 2-1, 2-2, and 2-3.	A				
44	Table 2-4	Please indicate that the reference elevation is the top of the casing and not the ground level. Please define the red value for MW-20 that is in parenthesis. Also, please confirm that the Depth to Clay Layer field represents the depth to the Wilcox clay as measured from the Reference Elevation.	C	The reference elevation is noted as the top of casing in the footnote. The table was corrected to reflect the difference between the ground surface and top of casing. There are no negative values in the table any longer. The depth to clay is the depth to Wilcox clay per the update CSM cross-sections.	D	Disagree. The comment has not been sufficiently answered. There is not a footnote that states TOC and is not clear if depth to clay is from TOC or from ground elevation.	C	The column headings for measurements made from the top of casing will be marked with an asterisk and the following footnote will be added at the bottom of the page: * indicates measurements are referenced to the top of the well casing.	A
45	Table 2-5	Table 2-5: Is this estimate mass for all groundwaters (shallow and Wilcox) and is the Army using the 2014 June isocontour Figure for the estimate? The pore volume should be multiplied by the average concentration to get a mass. EPA did not see thickness nor porosity incorporated into the calculations in the Table. Please redo the Table with the following: isopleth concentration, representative concentrations, area, thickness, volume, pore volume (multiply by porosity), and calculated mass.	C	The material balance was conducted for only the shallow zone aquifer. The June 2014 isocontours were used. The average thickness of the shallow zone aquifer and the porosity values are presented as footnotes to the table. The steps outlined by EPA were followed in the table. The volume of groundwater was calculated but not explicitly shown. The pore volume of groundwater for each isopleth contour line is added to the table. A mass balance equation is added at the bottom of the table to facilitate the calculations. A material balance for the Wilcox aquifer is added.	A	The RTC states the June 2014 iso-contours were used for calculations. Should it be from June 2016?	C	Yes, the June 2016 data were used (please see updated Table 2-5 in the Revised FS).	A
46	Page 2-6, Section 2.4.1, Third Para.	Please define ft^2 and yd^3 and add these to the acronym/abbrev page.	C	These units have been defined.	A				
47	Tables 2-5, 2-6, 2-8 and 2-9	EPA's understanding is that these represent the shallow groundwater only. The Tables need to clearly indicate this.	C	The table headers have been changed to reflect they belong to the shallow zone.	A				
48	Table 2-6	Are these calculations based on one of the figures included and does this include the areas inside and outside the containment area? Also, please include the sorption calculations in the Table. The kd (soil-water partition coefficient) values appear reasonable.	C	The information is provided in Section 2.4.2, fifth paragraph. The areas included in the figure are those enclosed by the isoconcentration lines, which encompass area both inside and outside the containment. An equation depicting the calculations for the sorbed mass in the saturated zone has been added at the bottom of the table.	A

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
49	Page 2-7, 3rd Paragraph, Last Sentence	Please provide a graph comparing well material type to chromium and nickel concentrations to support claim.	E	Deleted this statement because it is speculative in nature.	A				
50	Page 2-7	The FS presents mass calculations for MC, TCE and perchlorate in the shallow zone. While the depth of contamination is not known at all locations in the Wilcox formation, a mass calculation for the Wilcox formation aquifer should also be prepared, including data from 18CPTMW03SW and 18CPTMW22SW. This is needed because remediation of the Wilcox formation may be necessary, and the Army indicates that upward vertical gradients from the Wilcox formation to the shallow zone are present at certain locations due to extraction. Therefore, contaminants in the Wilcox formation represent a long-term source of groundwater contamination to the shallow groundwater system and need to be factored in the remedial design and estimates of remedial timeframes, plus costs.	C	Wilcox contamination mass balance has been prepared.	A				
51	Page 2-7	The FS indicates that the dissolved mass would increase with increased saturated thickness (i.e. pumping versus non-pumping conditions. It is possible that in higher water table conditions that dissolved mass would increase even more than predicted due to the dissolution/desorption of contaminants in the shallow zone. This possibility should be described.	C	This potential phenomenon was included.	A				
52	Table 2-7	Table 2-7: Please clarify if the porosity shown here is total or effective.	C	Clarified in the footnote that the porosity is total porosity.	A				
53	Table 2-8	What maps/reference are you basing these calculations on? If MW-9 or any other wells just to the west of the containment do include MC, then the first mass calculation may have to change. Was the 106,000 ug/l perchlorate value from 18CPTMW22 used in the calculation for the mass of perchlorate?		The information is provided in Section 2.4.2, fifth paragraph. As noted in the text, the areas included in the figure are those enclosed by the isoconcentration lines. The isoconcentration lines encompass area both inside and outside the containment.	A	Agree. However, EPA still believes the total mass calculation may be biased on the low side.	E/C	It is acknowledged that the mass estimates could be low in certain areas of the site. However, it is also noted that the high concentration in MW-14 is likely limited in aerial extent as illustrated by the low perchlorate concentrations in surrounding MWs screened in the Wilcox, therefore while some underestimate of calculated mass may be possible with respect to the overall distribution of mass in the subsurface the current estimate is believed to be suitable for use in evaluating the various potential remedial alternatives in this area of the site. The first complete sentence in the paragraph at the top of page 2-23 states: “For every one (1) foot increase in impacted thickness, the dissolved mass would increase by a factor of ~5%, assuming the groundwater concentrations remain unchanged.”	A

54	Table 2-11	ICTs 12A, 12B, 12C, ICT 4, and ICT 11 show detections of MC above the MCL. However, the MC plume is shown to be isolated to the northwest (ICT 12E and 12D, Figure 1-13). Well 129 was sampled, but it had a non-detect (located near 12C). If the ICTs in this area are showing MC, then there is some MC in groundwater in this area (though not extremely high, but above an MCL). The MC in 14D is reported at 19,000 ug/l indicating that the center of the plume shown on Figure 1-13 extends at higher concentration to the east near that ICT. EPA realizes these isopleths are based on well data collected and not on ICT data, but the ICTs can be used as a tool to see where higher concentrations are located on the boundaries of the site. There are higher concentrations of TCE and perchlorate in these ICTs than plume isopleths indicated from wells. The mass of the contaminants may be higher than calculated based on the values from these ICTs.	D	Data from most recent samples of January 2015 indicate no MC is present in ICT 12A, 12B, 12C, and ICT 4 (ICT 11 was not sampled), albeit, the reporting limits for some ICTs were above the MCL at 10 to 50 µg/L. Therefore, the depiction of the plume to the northwest based on well data provides a good representation of MC distribution. MC in 129 was < 5 µg/L in June 2014 (Figure 1-13) corroborating the concentration reported in 12C in March 2015 of < 50 ug/L. MC in ICT 14D in March 2015 was reported at 33.3 µg/L, well in line with < 50 µg/L reported in MW-21 in June 2014. MC was reported in ICT 14C at 8,280 µg/L in March 2015. ICT 14 C is bounded by 109 and MW-21 and both have below detection levels. Therefore, it appears that ICT 14C draws heavily contaminated groundwater from near MW-1/EW-01 area while the areas along the containment boundary indicate absence of MC.	A	Same comment as above.	C	Please see response to comment 53.	A
55	Page 2-9, Second and 3rd Paragraph	Please define MIP and CPT and add them to acronym list.	C	MIP and CPT have been defined and added to acronym list.	A				
56	Page 2-13, General Comment	The MC plume has shown a reduction in plume size since the implementation of the IRA based on the 1994 map. MW-7, MW-8, and MW-9 all have shown previous contamination of MC and these wells have not been sampled recently. Shaw sampled these wells just prior to the injection in 2007 and they did not detect any MC. However, a TVA sample taken from MW-9 (in 2009) had a concentration of 60,000 µg/l. Is there newer data since 2009 that indicates no MC in these wells? The following TCE concentrations were found by TVA in 2009; MW-7 (15,400 ug/l), 129 at 11,500 ug/l (2,730 ug/l in 2014), MW-8 (5,570 ug/l) and MW-9 (6,080 ug/l). Please note that the 2009 samples were collected right after a significant rain event. Please provide the most recent samples collected from these three wells to determine if there is still MC and TCE contamination in the western portion of the site.		MW-7, MW-8, and MW-9 were sampled for MC in December 2014 and were all < 5 µg/L. The June 2015 results for MW-7, MW-8, and 129 were 0.352 J µg/L, < 1.25 µg/L, and < 1.25 µg/L, respectively. TCE in these wells continue to be present and the depiction of the isopleth contours indicate the same. MW-7, MW-8, and MW-9 were sampled for TCE in December 2014 and the concentrations were reported at 1,880 ug/L, 1,180, and 3,030 µg/L , respectively. The June 2015 results for MW-7, MW-8, and 129 were 1,860 µg/L, 575 µg/L, and 509 µg/L, respectively.	A				
57	Table 2-13	Not for sure EPA understands the Table. Does this assume the full extent of the groundwater plumes? EPA is not clear on the last two estimations shown.		This information is described in Section 2.4.2.6. The estimated mass in formation is based on calculations completed in Table 2-5 for the dissolved phase, Table 2-6 for the sorbed phase,	A

				Table 2-7 for DNAPL, and Table 2-8 providing the mass of contaminants outside the containment for the dissolved and sorbed mass. The duration in years is based on the masses determined in the tables identified above and the mass extraction rates determined in Tables 2-10, 2011, and 2-12. These rates of mass extraction are presented in Table 2-13 as a footnote. The ratio of the total mass for a contaminant divided by the mass removal rate provides the estimated duration to remove the contaminant in years.					
58	Page 2-13, Last Paragraph	As stated in the text, a higher concentration of perchlorate (106,000 ug/l) was detected in 18CPTMW22. The well was later plugged due to a concern about the screened interval passing through the shallow zone and the upper Wilcox aquifers. An upper Wilcox was installed and now the concentration is almost an order of magnitude lower (17,300 ug/l). What is the LTM plan for the shallow zone in this area since there is no longer a monitoring well? EPA believes that the shallow zone in this area should be monitored by installing a new well.		A shallow well (18CPTMWR) near 18CPTMW22SW was installed in April 2016.	A	Agree. However, it appears that the new well (18CPTMW22R) is in the same perched zone (vertically) as well MW-20, which has low levels of perchlorate. The 106,000 ug/l in well 18CPTMW22 was found in a deeper vertical zone, so it still appears that this highly concentrated zone is not being monitored or considered.	C/E	Text and figures in the Revised FS have been modified to acknowledge 18CPTMW22R is screened in a perched zone above the shallow groundwater zone and therefore is not considered part of the shallow zone. A pair of wells screened in the shallow and deep Wilcox Formation is located just southeast of abandoned well 18CPTMW22. Based on the June 2016 perchlorate results, the shallow Wilcox well (18CPT22SW) had a concentration of 10,200 µg/L, but the deep Wilcox well (CPTMW22DW) had an estimated concentration of 1.21J µg/L.	A
59	Page 2-15, First Paragraph, Second Sentence	The text states *"The current depiction of the potentiometric lines in the shallow zone in the southern area of the site (Figure 1-6) consistently shows that there is no horizontal gradient to the south to facilitate migration of CoC's outside the containment area."* EPA disagrees with this statement. There are plenty of maps from GWTP quarterly reports and other reports that show there is the potential for groundwater flow to the south of the site. Even the map that is reference here still shows at least one potential flow path towards the south.	C/E	The text has been revised to replace "no" with "little", "…there is little horizontal gradient to the south to facilitate migration…"One could argue there is an element of flow from the high mounded area near 123 and AWD-2 to the south. However, the gradient becomes extremely flat near the southern corner of the site. Along with the extraction conditions in ICT 12A and ICT 11, little possibility exists for the contaminants to flow to outside the containment to the south.	D	The RTC states the text has been changed from "no" to "little", but the text in the revised FS does not include the modification to the text. The new shallow well, 18CPTMW22R, is completed in a perched zone which indicates a groundwater high. The new well is now being used to say there is no potential gradient towards the south in the shallow zone. EPA still believes there has been a history of a gradient towards the south. Numerous groundwater maps in the past have shown this gradient since the start of the pilot study. If there is no historical gradient to south, then how did the perchlorate reach the southwest corner of the site? In past meetings, the Army has stated the perchlorate originated from the site. Newer soil data collected in the southwest corner does not indicate any source area in the southwest area.	C	The text in the latest version of the Revised FS has been revised to replace "no" with "little", "…there is little horizontal gradient to the south to facilitate migration…" There is an element of flow from the high mounded area near 123 and AWD-2 to the south. However, the gradient becomes extremely flat near the southern corner of the site. Along with the extraction conditions in ICT 12A and ICT 11, little possibility exists for the contaminants to flow outside the containment to the south. It has been acknowledged in the revised text that monitoring well 18CPTMW22R is completed in a perched water zone and it was not used for contouring the shallow zone groundwater surface in revised Figure 1-6. Therefore, the off-site groundwater high previously shown in this area no longer exists and with its removal, the previous apparent steep radial gradient off of the high is no longer present.	A
60	Section 2.4.2.5	Estimates of vertical discharge and contaminant mass flux should be presented for areas of both downward (shallow zone to Wilcox formation) and upward (Wilcox formation to shallow zone) vertical gradients.	C	Estimates of mass flux across the Wilcox clay have been made at the locations identified in Section 2.4.2.5.	A

61	Page 2-17, Last Paragraph	The text states "Generally, the extraction rates increased in 2013 and 2014 compared to 2012 due to the fact the GWTP was not operational for nearly 4 months in 2012 as a result of scrubber system failure. This is primarily due to lower CoC concentration at the extraction locations, and not the amount of extracted groundwater, although groundwater extraction volumes are expected to be impacted by variations in precipitation patterns." There appears to be a disconnect between these two sentences and the intent of this discussion is not clear. Please revise.	C	Confusing portion deleted.	A				
62	Page 2-18, Section 2.4.2.7, COC Removal Rates	Site specific retardation rates should be presented for the site.	C	An attempt will be made to estimate general retardation coefficients for TCE and MC but application of an overall average could be problematic due to site heterogeneity and on-going extraction of GW.	A				
63	Section 2.5, Conceptual Site Model	The conceptual site model is a summary rather than a formulation of COC processes and the implications of the remedy.	C	Acknowledged.	A				
64	Page 2-19, 6th Paragraph	The Sale and Newell model should be referenced. *Sale, T. C., and C. Newell. 2011. Guide for Selecting Remedies for Subsurface Releases of Chlorinated Solvents. ESTCP Project ER-200530.* Also, the model did not determine the presence of DNAPL as stated in the report, it was determined from field data.	C	Reference added to reference list as indicated. Agree, the model is used to describe the presence of DNAPL.	A				
65	Figures 2-6	Please provide the information/references for the computations displayed in the Figures.		Tables 2-10 and 2-11 provide detailed account of how these mass fluxes were calculated.	A				
66	Figures 2-6a through 2-6c	The bars plotted in opposite directions above and below unity are confusing and unintuitive. Please consider an alternative presentation. The exponent values in the table are cut-off. Please correct.	C	The coordinates were corrected to eliminate bars displayed below unity. The table is expanded to display exponents in the table.	D	The current tables are not expanded enough to allow the reader to see the exponents.	C	In the Revised FS, the last three rows at the bottom of the graphs have been deleted because the information is redundant. It is provided at the top of each annual bar.	A
67	Section 3.2.1, Page 3-3	No TBCs were identified for this site?		No TBCs were identified.	A				
68	Page 3-4: Section 3.2.2.2	EPA disagrees with the statement pertaining to using industrials levels for chemicals without a MCL. EPA will require TRRP residential PCLs for contaminants without a MCL. Also, first use of TAC in the document, please define in the text.		Please refer to the response to Comment #12.TAC defined in 3.2.2.1 and acronym list.	A				
69	Page 3-6, First Paragraph	The reference identified here does not match up with the one in the reference list.	C	Reference corrected.	A				
70	Page 3-7	There are bald eagles at LHAAP, one flew near EPA's vehicle within a mile of the GWTP about 6 months ago. Also, the text at the end of first paragraph indicates that species confirmed at	C	Comment acknowledgement. Those species are not italicized.	A

		Longhorn AAP are marked in italic, but none of the species are in italic.							
71	Page 3-8, Section 3.2.5.2	Please define TSDF in text and add it to acronym list.	C	TSDF defined and added to acronym list.	A				
72	Table 3-1	EPA disagrees with the use of industrial PCLs for groundwater and surface water. Residential TRRP PCLs apply for contaminants without an MCL.		Please refer to the response to Comment #12.	A				
73	Table 3-7	Please include the equations and calculations that are used to estimate mass.	C	There is no Table 3-7. The equation to estimate DNAPL mass is included in the footnotes of Table 2-7.	A				
74	Page 4-1, Section 4.1, 1st Paragraph	Is there potential for contaminated surface water runoff from the site to the Bayou? The section also describes contamination in the shallow zone aquifer, but there is no mention of contamination in the Wilcox. Please modify to describe contamination found deeper in the Wilcox aquifer at the site.	C	A sample was collected by EPA from the site runoff to the north and the sample had no detection of contaminants. Wilcox contamination discussion was added to this section.	A				
75	Page 4.1, Section 4.1, 1st bullet	EPA disagrees, the shallow groundwater south of 18CPTMW22 is not defined. This section also does not mention the Wilcox aquifer contamination at this location.	E/D	Added information about soil data from borehole 18WW23 that did not detect perchlorate. Added additional information associated with perchlorate delineation efforts in March 2015 to delineate extent of perchlorate in this area. Added information about Wilcox aquifer in this section.	A				
76	Page 4-2, Bullets 3 & 4	Since these bullets mention soil areas that are not well defined, why not define them now instead of defining them during the RD. Also, these areas should not be sprinkled (only highly controlled) or saturated.	D	Limited extent definition to the south using data from 18CPTBB01 has taken place adjacent to 8A-940. Due to the shallow nature of impacted soil, it will be readily determined during the remedial design phase. Regarding location 8A-911, several soil samples were collected in the vicinity from 18CPTUEP09, 18CPTPB16, 18CPTPB17, and 18CPTUEP08 in 2015 that provide extent determination for MC and TCE in the unsaturated zone, although refinement of this extent remains.	A				
77	Page 4-2, Next to last Paragraph	The discussion about the perchlorate mass is not clear. Does the perchlorate timeframe assume no mass transfer rate from brine? Please revise and clarify.	E	There is no indication of the presence of brine at the concentrations identified in groundwater and saturated soil. The text will be revised to state "The basis for this assumption……18CPTMW22) does not support the presence of brine in shallow groundwater."	A				
78	Page 4-2, Table 2-13	How was the mass determined?	E	Please refer to response to comment 57 related to Table 2-13. Section 4.1 does not discuss how the mass is determined.	A

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
79	Figure 4-1	EPA does not believe that the sprinkling, as currently implemented, is beneficial for the site. It drives down contaminants vertically and spreads them further outward from the containment area in some areas such as the Northwest.		See response to Comment #3.	A/D	See comment number 3.		See response to comment 3.	A
80	Page 4-11, Section 4.4.1.3.4	The sentence "Extreme restriction of groundwater flow through the site could result in marginalization of groundwater extraction and containment recovery". What does this mean? Please explain.		If recharge of rainwater to the site is eliminated, the amount of groundwater that can be recovered will be diminished, which in turn reduces the max flux of removal of contaminants.	A				
81	Page 4-13, 1st Bullet	The bullet mentions that horizontal wells were not effective according to field experiments in the 1990's. Since advancements have been made to horizontal drilling since that evaluation, should this technology be re-visited? Also, please reference the statement on equivalent effectiveness of vertical and horizontal wells.	C/E	The statement about equivalency of effectiveness of vertical and horizontal wells has been removed from the text.	A				
82	Page 4-13, Last Paragraph	Please define EVO in text.	C	EVO definition added to the text.	A				
83	Page 4-13, 1st Paragraph	Biodegradation may not be first order and therefore constrained at the lower and upper limits. Therefore, it may not be easily observable at very low or very high concentrations.	C	Acknowledged.	A				
84	Page 4-16, Thermal treatment	The Report states that thermal treatment is not limited by subsurface heterogeneities like other treatments. Contrary to that statement, high flow zones have been problematic, as shown in the literature, because they transport the heat away from the targeted area.	D	Temperature distribution in the subsurface can be made more uniform based on the duration of application of thermal treatment. Additionally, the majority of chlorinated VOCs are present in fine-grained soils.	A				
85	Page 4-18, Last Bullet	Please define CEC in text and add to acronym list.	C	CEC has been defined in the text and added to acronym list.	A				
86	Page 4-19	Please define EZVI in text and add to acronym list.	D/C	EZVI is defined in the text. EZVI has been added to the acronym list.	A				
87	Page 4-23 Section 4.4.1.6.2	*"The hydraulic capacity of the plant has not been met so additional flow could be effectively handled."* What about the effluent? If Harrison Bayou is not flowing then there have been issues determining what to do with effluent. Additional effluent storage or some other engineered structure to hold the effluent water needs to be considered in this study.	D	There is not enough storage volume that can be practically designed to hold the GWTP effluent in excess of a few days. There have been occasions where discharge to Harrison Bayou was not possible for weeks due to lack of surface water flow, particularly during the summer months. The INF Pond could be deployed to manage discharge of treated groundwater when discharge to Harrison Bayou is not possible (e.g., due to low flow or treated groundwater quality exceeding discharge limits) and release to 18/24 via the sprinkler system is not possible (e.g., during periods of heavy rainfall). The text has been revised to acknowledge the use of the INF Pond for effluent storage when needed.	A/D	While it is good that the INF pond is added as an additional storage area when the effluent discharge is restricted by flow, the potential for building a larger storage tank still needs to be considered. One concern with the INF pond is it still functional and if you discharge to it what standards are applicable. In other words, the discharge to the pond may potentially be more restrictive if the concentrations of a contaminant are above MCLs/PCLs. Also, why is sprinkling on this site considered more acceptable than the other Longhorn sites which have no sprinkling?		Discharge standards for the INF Pond were agreed to by the FFA parties and are in the Administrative Record (Bate Stamp 024467). Limiting the area of discharge of treated wastewater from the GWTP to the site when it cannot be discharged to Harrison Bayou is considered good standard practice. Even though the water is treated, it is prudent to keep the treated water at the site where it was generated/treated. Also, please see response to comment #3.	A

88	Page 4-22	EPA agrees that arsenic mobilization is a concern with in situ bioremediation. In contrast, in situ oxidation would likely promote sorption of arsenic.	C	Comment acknowledged	A				
89	Page 4-25, Section 4.4.1.7.4	EPA recommends removing irrigation from Site 18/24. Irrigation can cause higher heads increasing the potential for migration downward and laterally towards the northwest corner where the Wilcox clay layer is absent.	D	See response to Comment #3.	D	See comment 3.			A
90	Page 4-37, Section 4.4.2.6	A slurry wall will require internal groundwater extraction to prevent downward migration of COCs.		Comment acknowledged.	A				
91	Page 5-3, Second Paragraph	The text here seems to contradict text on page 4-24 that states the current GWTP will be not be alternative. Please explain or modify the text?	C	Text modified to reflect that a new GWTP will be designed and installed. Section 5.2.2.1 discusses that a new GWTP will be designed and installed replacing the existing GWTP, however the existing GWTP will be used as an alternative.	A				
92	Figures 5-2	The text on page 5-3 states that wells 18CPTMW22, 18CPTMW23 (please note minor typo with the extra "W") and MW-8 will be converted to extraction wells. Please modify legend or well symbol on Figure to indicate these will be extraction wells. In addition, please note that ICT 3 and ICT 9 may be difficult to use due to bio fouling that occurred from previous injections.	E	No monitoring wells will be converted to extraction wells. The paragraph has been deleted.	A				
93	Page 5-4. Seventh Paragraph, Last Sentence	Please change "contaminated" to "contaminants".	C	Word correction completed.	A				
94	Page 5-4	It is difficult to assess remedial alternative discussion without better illustrations.	D	The text references Figure 5-2, which provides illustrations of remedial activities.	A				
95	Page 5-4	Based on recent results from the 18CPTMW22 (the new one that replaced the one that went through shallow and Wilcox) there is some significant perchlorate contamination. It appears the shallow zone aquifer in this area will be treated with ISB, but what about the contamination in Wilcox aquifer? The new well is being converted to an extraction well, so what is being used to clean up the perchlorate in this part of the Wilcox? In addition, how is the perchlorate contamination in the Wilcox in the northwestern corner being remediated?	C	No conversion to extraction wells will take place. Both the shallow zone and Wilcox aquifer will be treated with EISB. Similarly, the area to the northwest will be treated with EISB to treat for perchlorate. Because there is no clay in that area of the site, the shallow zone/Wilcox aquifer will be treated as one unit.	A

2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
96	Page 5-5, Sec. 5.2.2.1	Why are ICT-3 and ICT-9 to be placed online? Has simulations been done to show the benefit of this?		These two ICTs are located in areas of groundwater contamination where no groundwater capture is taking place. They fill a gap within the containment. ICT 3 is also located adjacent to the groundwater high and should help reduce this mounding condition.	A				
97	Page 5-5, Section 5.2.2.1	Based on the GWTP reports monitoring well 18WW17 has not been used for extraction for quite some time. Is it still operational?		Yes. The well was put back on line on January 17, 2016.	A				
98	Page 5-5, Section 5.2.1.1	EPA agrees that reactivation of some of the ICTs is a good idea to enhance contaminant removal and hydraulic control. However, some of the ICTs may have bio fouling which may limit their effectiveness. EPA recommends adding some new ICTs in the RD or some contingency cost estimates in case it is determined that new ICTs in certain areas may be more effective in reaching the clean-up levels in a quicker timeframe.	C	The efficiency of hydraulic recovery of the proposed ICTs will be tested and if fouling is causing concerns, attempts to clear the fouling will be implemented. If not successful, new ICTs would be installed. Cost provisions have been made.	A				
99	Page 5-6. 1ST Paragraph	It is not conservative/reasonable to assume zero retardation for mass removal estimates.	C	Retardation was introduced and the duration of time has been updated to reflect a more conservative approach.	A				
100	Page 5-9, Groundwater Monitoring and MNA	EPA believes that at the present time MNA is not a viable remedy, but maybe sometime in the future.	C/D	MNA is not a viable remedy for areas with high concentrations of dissolved contaminants, in areas in contact with sorbed mass within fine grained soils, and areas that contain DNAPL inside the containment. However, MNA is a viable alternative for low concentrations of contaminants in groundwater outside the containment in coarse grained soils. Examples include low concentrations (e.g., < 100 µg/L) of COCs in the Wilcox Formation. The discussion has been changed to focus on the concept introduced here.	A				
101	Pages 5-15 & 17	Please see comment Page 5-4 (applies to these alternatives as well).		Please see responses to those comments.	A

Appendix A Comments									
1	Add to Reference list	Please add to the following to the reference list: Plexus, 2005; USACE, 1993; and, Bradley and Chapelle, 1997.	C	Added references as applicable. Bradley and Chapelle, 1997 is not used in the document.	A				
2	Define and Abbreviations	Please define the following and add to the abbreviation list: ft., MNO and bgs.	C/E	Defined, where needed, and added these terms to the abbreviation list. MNO is not in the document.	A				
3	Page 2-3	Please define mg/L on this page. First time used.	C	Definition added on page 2-3.	A				
4	Page 2-5, Last Paragraph	Is the reference Hendrickson or Henderson (as shown in reference section)?	C	Corrected reference to Hendrickson.	A				
5	Page 2-7	Please add AEC to abbreviation list.	C	Definition added on Page 2-7.	A				
6	Page 2-8	Please define GWRTAC in text.	C	Definition on Page 2-8.	A				
7	Page 2-10	Please add SQL to the abbreviations list.	C	Definition added in acronym list.	A				
8	Figures A-1 through A-44	The legend indicates the cleanup level and initial concentration variables are in units of mg/L, whereas the "solutions" box uses units of ug/L. While EPA does not believe this effects the calculations, please correct the discrepancy in units.	C	The concentrations in the legend were changed to µg/L.	D	It appears the solution box is still in µg/L, while the rest of the figure is in mg/L.		That is correct.	A
9	Page 3-1, Section 3.1, Second Paragraph, General Comment	EPA believes that the pH went down in the region of MW-8 after some additional drilling in the area. The loss of cement or mud into the formation may have caused the low pH in the area.	E	Cement should raise the pH of groundwater. The low pH is symptomatic of the formation in associated with the presence of relatively high natural levels of iron.	A	Initial comment is not correct.			
10	Page 3-2, Second Main Paragraph	What effects would injection and irrigation have on the MNA calculations? It would seem that in certain areas where injection or irrigation has occurred, dilution would be a factor in a decreasing trend. In addition, injection may have caused movement of contaminants both laterally and vertically.	C	Previous injections of treated groundwater in ICT6 and ICT 9 cause dilution of contaminants within the influence of injection and would push contaminants away from the injection area. This was discussed as part of the CSM. Changes in concentrations caused by injection of water, will affect MNA estimates for those areas. Discussion associated with effect of injection on NA rates is introduced.	A	Reviewer could not find the original comment paragraph since there is no longer a page 3-2 in the Appendix. The response is fine.			
11	Page 3-12, Table	EPA recommends identifying the wells that are influenced by groundwater extraction and the ones not influenced to be noted in the summary table.	C	Added this information pointing potential influences of nearby extraction trenches.	A				
12	Page 3-15	Please define MCL on this page, first time used.	C	MCL definition added on page 3-15.	A	The MCL is actually defined on previous page 3-7.			
13	Acronym page (Appendix A)	Please remove DHC, DO, GW-IND, MARC, MSC, STEP, TBC, TCEQ, TOC, USAFCEE, and USGS from list since they are not used in text.	C/E	Removed these terms from acronym list, where appropriate. Added definition for DO in the text.	A

~~**Appendix B: PSI Addendum Comments**~~									
~~1~~	~~Page 1-2, Last Paragraph~~	~~Please use/include volumes or percentages of total water released to bayou verses injection/irrigation. The use of the word "occasionally" gives the impression that the majority of the time the water is released to bayou, but drought conditions has limited the times when water is released to the bayou.~~	~~C~~	~~Added information requested.~~					
~~2~~	~~Page 1-3~~	~~Private drinking water supply wells should be included in this assessment. For instance, Administrative Record Document No. 00076389 (Shaw RAB presentation slide) shows several off-site private drinking water wells – one of which (3524402) is located east of and potentially downgradient of LHAAP-18/24.~~	~~C~~	~~A water well survey is done and the map is introduced as an attachment.~~					
~~3~~	~~Page x, Third Paragraph~~	~~The text states "*In northwestern corner of the site, ICT-12E and ICT13A are at least partially not tied into the Wilcox clay and could potentially continue to allow contaminants of concern (CoCs) to migrate from within the containment area to outside the containment area. The results also confirmed the performance of the ICT and liners particularly to the southwest in preventing CoC migration within the containment. HIgh concentrations of perchlorate and TCE outside of the containment in the southwest area of the site were determined as a result of this investigation to related historical migration of CoCs prior to containment.*" Monitoring wells that have been sampled outside of the northwest corner are now detecting contamination that was not there before. Due to the proximity of the potential gap in containment in that area, one could conclude that this contamination is a result of the gap and other ongoing activities (accumulation of sprinkling) at the site. In addition, EPA disagrees that the southwest corner of the containment system has proven to be effective when a recently installed well outside of that corner detected perchlorate over 100,000 ug/l. There was limited or no data in that region prior to the installation of the new monitoring well, therefore, this statement is only speculative. The existing data in the report cannot support the conclusion that contamination was there before or that contamination was transported to that area after the installation of the collection system.~~	~~C/E~~	~~The stated information agrees with EPA's comments that gaps in the northwestern corner would allow migration of contaminants to off-site locations. Irrigation near that area of the site did not show evidence of change in groundwater potentiometric elevation and there is no evidence that irrigation is causing groundwater contaminant migration. Measures to distribute irrigation water are being implemented.~~ ~~A distinction between the southwestern site boundary and the southern corner of the site should be made. The discussion about current containment at the southwest boundary and historical migration of contaminants to outside that boundary is related to the southwest boundary of the site not the southern area (or corner) of the site where high perchlorate was discovered recently in 18CPTMW22 (plugged well) and the replacement shallow Wilcox well 18CPTMW22SW. We agree that the presence of perchlorate outside the southern corner of the site is likely historically present but cannot be confirmed with the collected information. A statement is added to that effect.~~					
~~4~~	~~Page 2-5, Section~~	~~Should the heading be 2014 Investigation instead of 2013 Investigation?~~	~~C~~	~~Header information changed to 2014.~~

	~~2.2.2.5.2~~								
~~5~~	~~Page 2-9, First Paragraph~~	~~The text states that soil samples were collected at the location near C-01 to determine presence or absence of perchlorate in shallow soils. During the review of the FS, a comment was made that no soil data exists in the area of the high perchlorate concentration near new well 18CPTMW22. That statement is still valid since C01 area is not close enough to the area of contamination, thus a soil data gap exists in this area. In addition, as stated previously, this location is still lacking a shallow well in the proper zone to monitor the high concentrations in the original monitoring well 18CPTMW22.~~	~~E~~	~~The soil data collected from attempted shallow well 18WW23 adjacent to C-01 provides a southern extent for the presence of perchlorate in the shallow zone. The FS (**Section 2.4.2.3** Lateral Extent and Migration of COCs) has since been updated discussing the soil data collected from 18WW23. Monitoring well 18WW23 was not installed due to the lack of water in this area of the site in the shallow zone.~~ ~~Soil samples were collected during drilling of 18CPTMW22SW borehole between 13 feet bgs and 31.5 ft bgs and analyzed for perchlorate to determine whether the soil and in particular the Wilcox clay is a source of perchlorate in this area of the site. Text has been added to indicate that soil samples were collected. The results/findings of this work are presented in Section 3.4.6. The analytical results are provided in Table 3-4.~~					
~~6~~	~~Section 2.2.2.3.2~~	~~Section 2.2.2.3.2 states that soil samples were collected from the Wilcox Clay at 18CPTMW22SW. EPA was not able to identify any data from these samples. Also see Table 2-2 – if soil samples were collected at 18CPTMW22SW, they should be included in Table 2-2.~~	~~E~~	~~Data for soil samples collected from the borehole of monitoring well 18CPTMW22SW were added to Table 3-4 and the results are discussed in Section 3.4.6. See response to Comment 5 for additional details.~~					
~~7~~	~~Section 2.3.3.3~~	~~Reference to the Chicot Formation is erroneous – please revise. The rationale for plugging 18CPTMW22 should be described in detail somewhere in this document.~~	~~C~~	~~Reference should have been to Wilcox. Text modification made. Rationale for plugging 18CPTMW22 is added to the text.~~					
~~8~~	~~Section 2.2.2.3.2~~	~~Change "…out diameter…" to "…outside diameter…"~~	~~C~~	~~Change made to "…outside diameter…"~~					
~~9~~	~~Section 2.3.2.2~~	~~Three what?~~	~~C~~	~~Corrected statement to read: "…three locations..."~~					
~~10~~	~~Figure 2-1~~	~~Certain CPT or CPT/MIP locations were completed using DPT due to access limitations. Figure 2-1 must accurately portray the type of subsurface investigation performed – not what was planned.~~	~~C~~	~~Figure 2-1 was modified by indicating that location 16 and 18 were DPT logs.~~					
~~11~~	~~Figure 2-3~~	~~The attempted shallow monitoring well location near C-01 (18WW23) should be illustrated on this or some other figure. Abandoned monitoring well 18CPTMW22 should also be illustrated on this or some other figure.~~	~~C~~	~~Added the requested information on this figure.~~					
~~12~~	~~Section 3, Page 3-1~~	~~"…information it to improve…" Please correct this typo.~~	~~C~~	~~Changed text to: "…information is to improve…"~~

~~13~~	~~Section 3.1.2.2.2~~	~~The bullet list formatting is confusing. EPA believes that the first and fourth bullets are the major headings. For clarity, the subsequent sub-bullets should be indented or reformatted with a different bullet style.~~	~~C~~	~~Agree. Changes made as indicated.~~					
~~14~~	~~Section 3.1.2.2.4, Page 3-6~~	~~"…noted "mottling: of the sediments." Change the ":" to a "".~~	~~C~~	~~Concur. Change made.~~					
~~15~~	~~Section 3.1.3~~	~~The water level contour maps (Figures 3-1 and 3-2) should include data from 18MW24, 18CPTMW03SW and 18CPTMW22SW, as applicable.~~	~~C~~	~~The information for those wells were added by displaying the December 2014 data instead of the June 2014 data in the report.~~					
~~16~~	~~Section 3.1.3~~	~~The Army has indicated that HDPE liners installed outside of the ICTs along the southwest and northwest sides of the containment area are sufficient to act as a barrier to prevent ICT extraction of groundwater located outside of these liners. Such a barrier would surely alter shallow groundwater flow patterns under both natural and pumping conditions. Has the presence of these liners been considered when contouring shallow groundwater elevations? If so, please explain why the impermeable liners do not appear to affect the shallow contours. For discussion purposes, EPA suggests that alternative shallow groundwater contour maps be prepared assuming no flow across the liners.~~	~~E~~	~~The presence of the liners has not been factored while contouring the potentiometric lines at the site for the shallow zone groundwater.~~ ~~It might be possible to draw the contours assuming the liners produce a complete cutoff of groundwater between inside and outside the ICTs. However, the groundwater level data do not support distinct groundwater flow patterns across the HDPE liners.~~					
~~17~~	~~Section 3.1.3~~	~~Is accurate water level data available from the ICT sumps? If available, these data could help inform/understand shallow groundwater flow patterns and contours in and around LHAAP-18/24 under current pumping conditions.~~	~~C~~	~~Concur with the concept. However, water levels in the ICT sumps are not collected due to obstruction of the presence of downhole equipment. Additionally, the sump pumps cycle on and off between the ICT probes low and high elevations. When the groundwater level inside the ICT sump decreases to the ICT probe low level which is set above the pump intake to protect the pump, the pump turns off and allows the water level in the ICT to increase. Once the groundwater level reaches the high water level probe in the ICT, the pump turns on and pumping begins. Therefore, measuring the groundwater levels in the ICT sumps are not going to provide information that would help understand the shallow groundwater contours because of the dynamic and transient conditions that occur in the sumps.~~					
~~18~~	~~Section 3.1.3~~	~~The text states that during the gauging events re-injection was not occurring but discharge to Harrison Bayou was occurring. The second quarter 2014 Quarterly Evaluation Report indicates that discharge~~	~~C~~	~~Text has been revised to reflect treated water release method at the time sampling was conducted.~~

2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]	Comment	C, D, E or X[1]	Response	A or D[2]
		~~to the Bayou only occurred for 15 days in May. The contour maps presented as Figures 3-1 and 3-2 were created from water level data collected in June 2014. The treated water was being sprinkled on LHAAP-18/24 at this time. It is probable that some recharge of shallow groundwater is occurring due to sprinkling. Please revise to accurately reflect water management practices at the time of water level gauging events.~~							
~~19~~	~~Figure 3-1~~	~~What is the hydrogeological basis for closed low elevation contours centered near or around MW-8, MW-16 and 18WW07? Army has explained that the HDPE liners prevent groundwater withdrawal in these locations so extraction does not seem to be a plausible explanation. The EPA finds the closed 167 ft. contour on the northeast side of the containment area (ICT-14C) to be plausible due to the lack of HDPE liners along this ICT wall.~~	~~E/C~~	~~These wells had lower elevations than surrounding wells and also crossed the 1-foot contour intervals used for plotting the data. Closed contours represent one interpretation of the results. It might be possible to open the closed contours along with using the ICT liners as cut off locations to reinterpret the groundwater flow. However, it is uncertain if this would be successful. For example, the contour line around 18WW07 may not be possible to open unless the contour at 168 foot elevation is also opened. In other words, the interpretation of the potentiometric line around 18WW07 is controlled by a set of wells surrounding this well; namely: 18CTPMW19, 18WW08, and 18CPTMW16 and a different interpretation may not be plausible.~~ ~~Agree with EPA's interpretations about the effect of extraction in the northeastern ICTs on the potentiometric interpretation.~~					
~~20~~	~~Figure 3-1~~	~~Shallow groundwater contours appear to ignore the presence of Harrison Bayou. Regardless of whether or not the bayou is acting as a gaining or losing stream (or both) in this area, it seems implausible that groundwater surface water interactions along the bayou would not alter shallow groundwater contours in some fashion. Please explain how Figure 3-1 represents an accurate depiction of conditions in this area. The EPA observes that the potentiometric surface maps presented in the fourth quarter 2014 Quarterly Evaluation Report appear to handle this better by terminating the contours before crossing the bayou.~~	~~C~~	~~Concur with EPA that SW/GW interaction would alter the contours in this area of the site. Figure 3-1 is redrawn with this in mind.~~					
~~21~~	~~Figure 3-2~~	~~What is the hydrogeological basis for the closed 167-foot elevation contour to the southwest of the containment area?~~	~~C~~	~~Contours have been redrawn to avoid presence of artificially closed contours.~~					
~~22~~	~~Section 3.2.3~~	~~The text describes soil samples collected at depths of 6, 12 and 16 ft bgs at the location of proposed well 18MW23 with no detections of perchlorate. Army asserts these data demonstrate that there was no~~	~~C~~	~~Added text to this section and elsewhere in this document and in the Revised FS to provide specific information about the data collected. The proposed well location has been added to Figure 2-3 in~~

		~~shallow groundwater perchlorate migration to this location from source areas. While EPA does not dispute this conclusion, additional details regarding the depths of these samples relative to the Wilcox Clay should be provided to further substantiate this claim. The location of proposed well 18MW23 should be shown on a map and the results presented in a table. Is a log for this well provided in Attachment A?~~		~~response to Comment 11. The results are indicated in Table 3-4 and the reference to the table in the text has been added. Additionally, the boring log is presented in Attachment A as 18WW23DPT and the reference has been added in the text.~~					
~~23~~	~~Section 3.2.3, Page 3-14~~	~~The discrete groundwater samples at 18CPT15 represent a snapshot in time. Wells 18CPTMW23 and 18CPTMW15 have elevated concentrations of perchlorate and TCE. No Wilcox Clay is present and downward vertical gradients are generally present outside of the containment area. EPA agrees that at least one Wilcox formation well is needed in this area as described in Section 3.5.3.~~	~~E~~	~~The proposed well 18WW24 has been installed to delineate extent of perchlorate laterally. Since the groundwater level between the shallow zone and the Wilcox Formation is very similar (example C-02 in the shallow zone has an elevation of 169.50 ft amsl and the adjacent Wilcox well MW-13 has an elevation of 169.31 ft amsl; another example 18WW08 in the shallow formation has an elevation of 169.07 ft amsl and adjacent Wilcox well 18WW09 has an elevation of 169.04 ft amsl) in that area of the site, there appears to be a very slight downward vertical gradient between the shallow zone groundwater and the Wilcox Formation groundwater, which is a reflection of the continuous nature of the water column in these areas where the Wilcox clay is absent. Additionally, the discrete groundwater data collected from 18CPT15 at depths of 14-18 ft bgs, 25-29 ft bgs, and 38 to 42 ft bgs for perchlorate and TCE presented in Table 3-5 clearly indicate rapidly decreasing concentrations of perchlorate and TCE with depth (e.g., perchlorate concentration decreased from 2,620 µg/L at 14 to 18 ft bgs to 87.5µg/L at 25 to 29 ft bgs, and further to 6.16 µg/L at 38 to 42 ft bgs (Wilcox Formation sample). Also, 18CPTMW15 (and 18CPTMW23) straddles both formations which negate the need for a Wilcox Formation well. Finally Wilcox Formation monitoring wells 18WW02 and 18WW09 in that area of the site have reported perchlorate concentrations of 0.216 µg/L and 0.125 µg/L, respectively in June 2014 and monitoring well 18WW24 had a reported perchlorate concentration of 0.439 µg/L in December 2014. Therefore, perchlorate delineation to the northwest area of the site in the Wilcox Formation is complete.~~					
~~24~~	~~Figure 3-10~~	~~As demonstrated in the fourth quarter 2014 Quarterly Evaluation Report, data from monitoring wells 18CPTMW03SW and 18CPTMW22SW considerably change the isoconcentration contours for~~	~~C/E~~	~~The December 2014 data and maps have been introduced in the PSI report to take advantage of the data from the three new wells 18CPTMW03SW, 18CPTMW22SW, and 18WW24. Note that the~~

		~~perchlorate, TCE and MC in the shallow Wilcox. These data must be included to ensure the FS adequately evaluates/addresses the need for potential groundwater remediation in the shallow Wilcox formation. The substantial changes to these contours will also affect the calculations of contaminant mass presented in the FS, which may affect estimated remediation timeframes. EPA assumes that the Wilcox mass was calculated in the FS. Is this correct?~~		~~concentration reported in 18CPTMW03SW in December 2014 for MC is very negligible (59 µg/L) compared to 32,400 µg/L in 18CPTMW01SW and therefore, has negligible effect on the mass of MC in the Wilcox Formation. Similarly, TCE concentration in 18CPTMW03SW at 1,010 µg/L is small compared to 16,800 µg/L in MW-14 and does not affect the total mass of TCE in the Wilcox Formation appreciably. Finally for perchlorate the picture is very similar to MC and TCE whereby the detection of perchlorate in 18CPTMW03SW at 5,880 µg/L is small compared to perchlorate in MW-14 at 261,000 µg/L and 50,000 µg/L in 18CPTMW08SW. Additionally, perchlorate detection in 18CPTMW22 was known previously and was factored into the FS assessment. Current remedial action includes the Wilcox Formation areas near 18CPTMW08SW and MW-14 where the highest perchlorate and TCE concentrations reside. Shallow zone remediation is targeted at 18CPT15 and 18CPTMW22 areas.~~					
~~25~~	~~Section 3.2.3, Page 3-14~~	~~This section describes perchlorate contamination in the shallow Wilcox. Perchlorate concentrations in MW-14 are not mentioned. This well consistently has some of the highest concentrations in the Wilcox formation and should be described in the text. The elevated perchlorate concentrations at abandoned shallow well 18CPTMW22 and new Wilcox well 18CPTMW22SW, along with elevated perchlorate data from ICT-11 and ICT-12A and ICT-12B suggest the presence of a possible continuing perchlorate source area in the southwest quadrant of the containment area independent of source areas previously identified in this document. The EPA observes two former buildings in the southwest quadrant of the LHAAP-18/24 – Buildings 24-X and 25-X. Historical records indicate these buildings contained wash racks used for washing containers containing contaminated wastes, including explosive wastes. Given the high solubility of perchlorate, if perchlorate residues were washed from drums in this area, significant concentrations may have been released to the environment. Feasibility Study Figure 1-5, shows a depression in the Wilcox clay surface below this area. Concentrated perchlorate brines, if released, could have migrated down into this depression, pooled and migrated into the fine grained~~	~~C~~	~~Agree that the perchlorate source in the area to the south of the site is independent from other perchlorate areas and should not have been mapped as a single contiguous plume across the site as depicted in the 4th quarter 2014 report as described in Comment 24. The presence of wash racks in that area of the site is well known and is the cause of high perchlorate in this area. The extent of perchlorate in the shallow zone to the south has been defined by the clean soil data from location 18WW23 adjacent to C-01 as discussed above in response to Comments 5, 6, and 22. Additionally, as described in the revision to the text in Section 3.4.6, as depicted in Table 3-4, and in response to Comments 5, and 6, soil data have been collected from the borehole of 18CPTMW22SW at 10 discrete locations and analyzed for perchlorate. The results as described in Section 3.4.6 indicated that perchlorate is not sourced from the Wilcox Clay and that the majority of perchlorate is in the groudnwater. Figure 1-5 of the FS does not show a depression, it rather shows that flow gradient is towards that area of the site and then farther to the south. The impression of the depression is because the well is~~

		~~clay, representing a long-term continuing source to the groundwater. Please identify all investigations and data, if any, indicating these releases from these buildings and related sumps are not potential sources of the perchlorate contamination observed in this area of the site. If sufficient information is not available, then additional site characterization may be needed in this area.~~		~~at the edge of the contoured area. A better depiction of the Wilcox clay pattern is presented in cross-section D-D' presented in Attachment B. The cross-section does not show the presence of a depression in the Wilcox clay at this location. Note that if the concept of accumulation of perchlorate brine within this "depression" area has occurred, perchlorate in soil samples collected at 18CPTMW22SW would be very high. The highest perchlorate concentration in the Wilcox clay at location 18CPTMW22SW is 1,410 ug/kg (see Table 3-4) which is hardly a concentration representing perchlorate brine.~~ ~~Finally, two soil samples (18-SB08 at 10 to 12 ft bgs and 16.5 to 17.5 ft bgs) were collected in August 2011 and the perchlorate results were < 1.27 ug/kg and < 1.22 ug/kg, respectively. The borehole location is identified in Figure 1-4. The borehole was drilled within former sump 25-X, which is depicted in Figures 1-3 and 1-4. These results indicate there is no source of perchlorate in the soil.~~ ~~Therefore, this hypothesis is not substantiated and no further action would be required.~~					
~~26~~	~~Section 3.2.4.4~~	~~December 2014 perchlorate and TCE concentrations in well 18CPTMW03SW were 5,880 and 1,010 ug/L, respectively. This document should be updated to include these data so that the FS considers all available data.~~	~~C~~	~~Information updated.~~					
~~27~~	~~Section 3.2.4.12, Page 3-20, Last Paragraph~~	~~Clay elevations appear to be reported as both feet amsl and feet bgs. The EPA is not aware that the Wilcox Clay is found 157 ft. bgs, as indicated. Also, the sentence containing "…migrate to the north towards 18CPT25 to the north…" should be revised to remove the double reference to direction.~~	~~C~~	~~The reported elevation in fee bgs should be in feet amsl. Correction to the text was made.~~					
~~28~~	~~Section 3.4.6~~	~~December 2014 sampling results indicate a perchlorate concentration of 17,300 ug/L at 18CPTMW22SW. The presence of high concentrations of perchlorate in the shallow Wilcox outside of the containment area may warrant remedial action. Appendix B should be updated to reflect this finding so that the FS is based on all available information.~~	~~E~~	~~Section 3.4.6 was updated to reflect the concentrations of perchlorate in the soil samples that were collected at this location from borehole 18CPTMW22SW. The maps have been updated to reflect December 2014 results. The presence of high perchlorate in the shallow Wilcox at this location will be addressed in the FS as needed.~~					
~~29~~	~~Section 3.5.3~~	~~The EPA concurs that a Wilcox formation well is needed at this location; however, it is not clear from the text if Army is proposing a shallow Wilcox or~~	~~E~~	~~Please see response to Comment 23. No Wilcox well is required in this area of the site and the text is modified to reflect this position with additional~~

		~~Deep Wilcox well? More than one Wilcox well may be needed.~~		~~details providing justification for this conclusion. Note that 18CPTMW15 is mostly screened in the Wilcox Formation and an additional Wilcox Formation well would not be required due to the presence of low concentration of perchlorate below the medium-specific concentration of perchlorate of 26 ug/L at a depth of 38 to 42 ft bgs form the discrete water sample collected in March 2013.~~					
~~30~~	~~Section 3.5.4~~	~~Water level and chemical data are now available for this well and should be included in this addendum. The EPA recognizes that the available data indicate contaminants have not migrated to this location above applicable criteria and the FS is not affected by the lack of this information.~~	~~C~~	~~Text updated with December 2014 results.~~					
~~31~~	~~Section 3.8.3~~	~~Arsenic, barium and chromium are not chemicals of potential concern. They are chemicals of concern.~~	~~C/E~~	~~Agree for barium and chromium but not for arsenic. Arsenic was not considered as a CoC at this site.~~					
~~32~~	~~Section 4.1.2, First Bullet~~	~~The EPA did not comment previously on the detailed evaluations presented for each location. The descriptions used to substantiate Army's conclusions regarding source areas were extremely difficult to understand and conceptualize and, based on the information provided the EPA cannot conclude that impacted soils within the purported smear zone are not source areas due to their interaction with and sourcing from groundwater. Alternative, preferably graphical demonstrations are needed to support Army's position. One suggestion is that potential source area elevations (e.g. tops and bottoms of contaminated interval) be plotted with groundwater hydrographs for supporting wells to demonstrate that these contaminated soils are consistently within a smear zone and potentially sourced by groundwater. Other graphical demonstrations may be as or more effective.~~	~~E~~	~~The same information is provided in tabular format (see Tables 3-3 and 3-4).~~					
~~33~~	~~Section 4.1.3~~	~~The EPA concurs with the assessment that contamination could migrate below or between the ICTs 12E and 13A. Based upon extremely high perchlorate concentrations in 18CPTMW22, the EPA also believes that bypass may also be occurring between ICT-11 and ICT-12E. Furthermore, perchlorate data from 18ICTMW22SW demonstrates elevated impacts to the Wilcox formation. It cannot be concluded if these represent historic impacts prior to ICT installation or represent continuing migration.~~	~~E~~	~~Added language to reflect the information provided by soil data from 18-SB08 and 18CPTMW22SW, which implies that perchlorate is no longer sourced from the unsaturated soil and that the majority of perchlorate in the saturated zone is present in groundwater.~~					
~~34~~	~~Section 4.2~~	~~Please see earlier comments regarding the need to~~	~~C~~	~~Added text to introduce those wells and their~~

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
		RTC	Accept all RTC.	--	Noted.	A
1	1-6	1.5, 1st Paragraph	Sentence beginning with "Caddo Lake State Park operates" should reference 18/24 at end of sentence.	C	Missing site number (18/24) has been added to the end of the sentence.	A
2		Figure 1-6 and references to MW-20 and 18CPTMW22R	This area of the site is odd, but it needs to be dealt with consistently. We should not include one of these wells and disregard the other for contouring and discussions of gradient or contaminant migration. Suggest a technical discussion to determine how to deal with data in this area and what it means.	C	Both monitoring wells MW-20 and CPTMW22R are completed in a small perched groundwater unit that is not in direct hydraulic communication with the Shallow Zone groundwater. Therefore, the groundwater elevations for these two wells were not included when the Shallow Zone potentiometric surface was re-contoured. Figure 1-6 was revised accordingly and includes a note indicating the groundwater elevations for MW-20 and CPTMW22R were not used for Figure 1-6. This information was also added to the text in Section 2.4.2.3 in response to TCEQ comment 7.	A
3		Figures that display Isopleth contours for Wilcox	Between one version and another, all of these Wilcox figures changed from a nice readable color, for well numbers and concentrations, to the orange hash-mark color that is really difficult to read. Please change them back to a solid color. Black would be great. Please talk to the map maker and ask him/her not to use this color.	C	All figures in the revised FS with symbols that were orange/ hash marked have been replaced with darker, easy to read symbols.	A
4	2-2	2.1.2	Sentence beginning with "Since groundwater is being restored" has some typos - "discussion of" and revise this clause to "risk to a hypothetical"	C	Typographical errors were corrected as indicated.	A
5	2-4	2.2.2	First paragraph – Sentence beginning with "After dispute resolution" add "in absence of MCL" to end.	C	"in the absence of an MCL" has been added to the end of the indicated sentence.	A
6	2-16	2.4.2.3	First paragraph – formatting strangeness in print version and "clay liner" should read "clay layer"	C	Spacing issues have been corrected and "liner" has been changed to "layer" as indicated.	A

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
7	2-17	2.4.2.3	References to MW-20 and 18CPTMW22R, see comment 2. Also, if not hydraulically possible for contaminants to move here with groundwater, where did they come from? Suggest revision of sentence to something a little less absolute.	C	The discussion in this section (2.4.2.3) and elsewhere in the document concerning the groundwater surface high associated with MW-20 and 18CPTMW22R has been changed to indicate that the elevations in these wells reflect the groundwater surface of a perched unit, not the Shallow Zone groundwater. Related Shallow Zone potentiometric surface maps have been re-contoured without the groundwater elevations from the perched wells. The June 2016 sample results for CPTMW22R (perched groundwater) for all VOCs and 1,4-dioxane are below the detection limit and perchlorate was detected at 0.917 µg/L, well below the PCL of 17 µg/L. In the second to last sentence on page 2-16 “no” has been changed to “little” in response to an EPA comment and the text that follows has been modified to indicate that there is no Shallow Zone groundwater surface high at 18CPTMW22R. The absence of Shallow Zone groundwater mounding in this area is consistent with historical monitoring results in this area and a scenario where COCs in Shallow Zone groundwater migrated to the southwest part of the site before installation and operation of the extraction system.	A
8	2-23	2.4.3.3	Last paragraph – Sentence beginning with “Only arsenic” to clarify add “For metals,”	C	“For metals” has been added to the beginning of the indicated sentence.	A

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
9	5-5	5.2.2	Last paragraph – Briefly note the decision criteria for deferring and later initiating removal of soil under UEP. Why defer? What criteria later indicates it is time to remove or leave in place?	C	The current language has been modified as follows: "Removal of contaminated soil under the UEP may be performed as a contingent remedy in the future, if conditions change such that it poses an imminent threat to human health or the environment. Currently however, the existing cap effectively prevents human contact with contaminated soil, and minimizes infiltration of precipitation/runoff that could potentially mobilize COCs in the waste and impact shallow groundwater. The cap is regularly maintained and inspected to ensure its continuing effectiveness. If in the future, groundwater monitoring detects a significant increase in COC concentrations in wells downgradient of the UEP, and/or the water table elevation rises significantly, causing a large part of the underlying waste to become saturated, a detailed evaluation would be performed to assess the need for a contingent remedy, either for the soil or for the groundwater. The RD will address the triggering criteria for evaluating whether a contingent remedy is needed".	A

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]
~~33~~	~~1-3~~	~~Bullets at top of page~~ ~~Add sentence to include revisions to the modifications. Current narrative makes it look like injection is still happening.~~	~~C~~	~~Added text to update information that reinjection is not being practiced.~~	
~~34~~	~~2.2.2.4.1, 2-4~~	~~First sentence needs some commas.~~	~~C~~	~~Sentence modified to provide clarity of content.~~	
~~35~~	~~General~~	~~Look for Draft IWWP and revise~~		~~Revised as Final.~~	
~~36~~	~~2.2.5.2, 2-5~~	~~Should be titled "2014" investigation~~	~~C~~	~~Changed header to 2014.~~	
~~37~~	~~2.3.3.3, 2-13~~	~~2014 – Is reference to "Chicot" correct here?~~	~~C~~	~~Should reference Wilcox. Correction made.~~	
~~38~~	~~3-44~~	~~Last paragraph should start section 3.2.4.63 with section heading~~	~~C~~	~~Added a new Section for 18CPTPB17.~~	
~~39~~	~~3.4.4, 3-51~~	~~Last sentence~~ ~~TCEQ agrees that data gaps remain in this area and additional delineation is required. This information should also be included in the feasibility study~~	~~D~~	~~Section 3.4.4 pertains to 18CPT24 location located near the eastern corner of the site. The last paragraph of this section pertains to 18CPTMW22SW located near the southern corner of the site. Therefore, the last paragraph was deleted. Instead see Section 3.4.5 and 3.4.6 pertaining to the area in the vicinity of~~	

Responses to Comments on
Draft Feasibility Study for LHAAP-18/24, Burning Ground No. 3 and Unlined Evaporation Pond
Longhorn Army Ammunition Plant, Karnack, Texas

27-February 2015

Reviewer: April Palmie, TCEQ

Respondent: Marwan Salameh, AECOM

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Section/Page Reference	Comment	C, D, E or X[1]	Response	A or D[2]
				~~18CPTMWW22SW.~~	
~~40~~	~~3.5.3, 3-54~~	~~Conclusion sentences~~ ~~TCEQ agrees that data gaps remain in this area and additional delineation is required.~~	~~C~~	~~Additional delineation was completed as described in added text to this section and as described in ensuing **Section 3.5.4** describing installation of MW-18WW24.~~	
~~41~~	~~4-2~~	~~(Similar to comment 29)~~ ~~Relevant bulleted statement should also include discussion of groundwater concentration.~~	~~C~~	~~The reference should be to Comment 30. Added groundwater data from nearest sample/well location for each bullet.~~	
~~42~~	~~4.2.1, 4-4~~	~~(Similar to comment 30)~~ ~~Explain why 18CPTMW22 was plugged.~~	~~C~~	~~The reference should be to Comment 31. Explanation added.~~	
~~43~~	~~Attachment A~~	~~Thank you for adding cross-reference cover page.~~	~~C~~	~~Thank you.~~	
44	Appendix D	Cost build-ups are missing detailed costs for EISB (all relevant), slurry wall construction (Alternative 3), and thermal treatment (Alternative 5). These seem to be included on the first page of each cost build-up (by year) but not on the following pages (by task).	C	Added details for the EISB, slurry wall construction, and thermal treatment to the various alternative detailed cost sheets.	A

EXECUTIVE SUMMARY

This Feasibility Study (FS) has been prepared by AECOM Technology Services, Inc. (AECOM) on behalf of the United States (U.S.) Army Corps of Engineers (USACE), Tulsa District, under the Huntsville District's Worldwide Environmental Remediation Services Contract No. W912DY-09-D-0059 Task Order No. DS01, for remediation activities at the former Longhorn Army Ammunition Plant (LHAAP) located in Karnack, Texas. This FS presents the analysis of remediation alternatives for the Burning Ground No. 3 (designated as LHAAP-18) and the Unlined Evaporation Pond (UEP) (designated as LHAAP-24) in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA), and provides a basis for remedy selection to address potential risks to human health and the environment consistent with the intended future use of LHAAP as a national wildlife refuge.

Background

LHAAP is an inactive, government-owned, formerly contractor-operated and maintained Department of Defense facility located in central-east Texas. LHAAP operated until 1997 when it was placed on inactive status and classified by the U.S. Army Armament, Munitions, and Chemical Command as excess property.

LHAAP-18/24 is a fenced, cleared area consisting of 34.5 acres in the southeastern section of LHAAP. LHAAP-18/24 had been used since 1955 as a burial and burning ground for various industrial and hazardous wastes generated at LHAAP. The UEP was no longer used after 1984, and was closed under the Resource Conservation and Recovery Act in 1986. As part of the LHAAP-18/24 Interim Remedial Action (IRA), approximately 32,000 cubic yards of soil were excavated and treated by low temperature thermal desorption. A groundwater extraction system incorporating approximately 5,000 feet (ft) of interceptor trenches and a groundwater treatment plant was installed in 1997 to control the migration of contaminated groundwater. This treatment system is still operating.

LHAAP was placed on the National Priorities List (NPL) on August 9, 1990. A Federal Facility Agreement (FFA) became effective on December 30, 1991, among the U.S. Environmental Protection Agency (USEPA), the U.S. Department of the Army (U.S. Army), and the Texas Water Commission (later named the Texas Natural Resources Conservation Commission, now named the Texas Commission on Environmental Quality [TCEQ]). LHAAP-18 and LHAAP-24 were listed as NPL sites in the FFA due to threatened releases of hazardous substances, pollutants or contaminants.

The entire LHAAP installation was under the control of the U.S. Army until May 5, 2004, when approximately two-thirds of the property was transferred to the U.S. Fish and Wildlife Service. Property transfer continues as response actions are completed at smaller parcels of land. The U.S. Army Environmental Command provides funding for the environmental remedial activities. The Base Realignment and Closure Division is responsible for all aspects of LHAAP including the environmental program, operations, and land transfer.

Harrison Bayou watershed is the nearest significant surface water body to LHAAP-18/24. Runoff from the site drains into Harrison Bayou, which eventually flows into Caddo Lake (a drinking water source for multiple communities).

Sampling specific to LHAAP-18/24 was conducted as referenced in Jacobs Engineering Corporation (2001) in 1980 (U.S. Army Environmental Hygiene Agency), in 1982 and 1987 (Environmental Protection Systems), and in 1986 (Camp, Dresser, & McKee). Following those initial investigations was the multiphase Remedial Investigation (RI) (Jacobs Engineering Group, Inc.). Additional investigations were performed through 2008 (Solutions to Environmental Problems, Inc., Plexus Scientific Corporation, and Shaw Environmental, Inc. (Shaw)). A limited source assessment was conducted in August 2011 (Shaw) and additional investigations were conducted in 2013, 2014, and 2016 (AECOM) in an attempt to improve the Conceptual Site Model and assess for the presence of source areas (unsaturated soil and residual dense non-aqueous phase liquid (DNAPL) in the saturated shallow zone). The results of the 2014 investigation were compiled with the 2013 investigation and documented in the Final Updated Post-Screening Investigation (PSI) Report (AECOM, 2016a). The 2016 PSI results were compiled and presented in the Draft Final Supplemental to the Updated PSI Report (AECOM, 2016c) (**Appendix B**). Currently, groundwater at LHAAP-18/24 is monitored semi-annually, associated with operation of the existing groundwater extraction and treatment system.

The investigation data available for the site identified impacts to soil, shallow groundwater, and the Wilcox Formation. The majority of impacts to the soil (i.e., source areas) were removed in the 1997 IRA where approximately 32,000 cubic yards of soil were removed. The major concern associated with the presence of contaminants of concern (CoCs) in the soil is associated with potential soil leaching to groundwater. Compilation of analytical results from historical and recent data overlain on areas of soil removal produced a map of potential residual soil source areas. These areas are isolated to the west and south of former Air Curtain Destructor (ACD), and to the south, west, and beneath the UEP. Analysis of the data indicated the majority of CoCs in the soil of these areas do not constitute source areas because either 1) the soil was identified to be present within the groundwater zone (i.e., saturated zone), such as to the west of the ACD, 2) data indicate the soil concentration decreases with depth and does not constitute a source, such as to the south of the ACD, or 3) the impacted soil is located within the UEP, which prevents infiltration and potential migration of CoCs from soil to groundwater. The only areas where exceedances exist are to the south of the UEP (in the vicinity of 18SB02 and 8A-911 from 8 to 12 ft below ground surface (bgs) and in the vicinity of 8A-975 between 5.5 and 12 ft bgs) and to the west of the UEP (in the vicinity of 18CPTBB02 and 8A-940 between 4 and 10 ft bgs and in the vicinity of 18SB04 between 10 and 14 ft bgs). Although the soil beneath the UEP is protected by the UEP cap, this soil could constitute a source of CoCs to groundwater and is addressed in this Revised FS.

CoCs were detected in monitoring wells within the shallow groundwater bearing unit (formerly designated as shallow and shallow/intermediate zones), and occasionally in the Wilcox Formation (formerly designated as intermediate and deep zones). The shallow zone and the Wilcox Formation are separated by a Wilcox clay unit present over the majority of the site, with the exception of the area to the northwest. The clay layer is also absent to the north of the site approaching Harrison Bayou.

Risk Assessment

The baseline human health risk assessment for LHAAP-18/24 is based on data from the RI and additional investigations performed through 2001 (Jacobs, 2002). The future use of

LHAAP-18/24 is as a national wildlife refuge as a part of the Caddo Lake National Wildlife Refuge. The human health exposure scenario for LHAAP-18/24 is a hypothetical future maintenance worker. Groundwater at LHAAP-18/24 presented a cancer risk of 4.4×10^{-1}, which exceeds the acceptable cancer risk range of 1×10^{-6} to 1×10^{-4}. Groundwater contaminants determined to be CoCs due to cancer risk were methylene chloride (MC), trichloroethene (TCE), and chloroform. The total hazard index (HI) from groundwater was 3,200, which exceeds the acceptable HI of 1. Groundwater contaminants determined to be CoCs due to noncancer health hazards were MC, TCE, perchlorate, chloroform, and cis-1,2-dichloroethene (DCE).

For chemicals in groundwater posing unacceptable risk or hazard, USEPA maximum contaminant levels (MCLs) are utilized as cleanup levels. In the absence of federal drinking water standards, cleanup levels will be based on the Texas Risk Reduction Program (TRRP) Tier 1 Groundwater Residential Protective Concentration Levels (PCLs), hereby referred to in this document as “TRRP PCLs” or “PCLs”.

Certain groundwater contaminants were selected as CoCs due to historical MCL exceedances that have not been superseded by more recent sampling results. These included tetrachloroethene (PCE), benzene, 1,1,2-trichloroethane (TCA), barium, chromium, and thallium. Chemicals were not selected as CoCs if they were found to be naturally-occurring or if exceedances of MCLs or the groundwater Texas Risk Reduction Standard 2 medium-specific concentrations (MSCs) for industrial use (GW-Ind) in early sampling were not confirmed in later events.

Additional screening of potential CoCs was conducted as additional groundwater data in the Shallow Zone and Wilcox Formation were collected. Compounds such as chloroform which are sporadically detected with highest concentrations below the TRRP PCL were eliminated from the list of CoCs. Thus, the groundwater CoCs for the Revised FS are: MC, TCE, perchlorate, cis-1,2-DCE, 1,4-dioxane, PCE, benzene, 1,1,2-trichloroethane (TCA), vinyl chloride (VC), bromodichloromethane, 1,3,5-trinitrobenzene, antimony, barium, chromium, and nickel. Bromodichloromethane, 1,3,5-trinitrobeznene, arsenic, and cobalt have been retained on a provisional basis, because the concentrations above the PCL are only detected sporadically (cobalt), no recent results are available (1,3,5-trinitrobenzene), detection limits for recent results were above the cleanup levels (bromodichloromethane), or the CoC is not associated with the site (arsenic). These provisional CoCs will be re-evaluated when additional data are collected with lower reporting limits. 1,4-Dioxane has been added as a COC as a result of its detection in several wells across the site above the TRRP PCL.

The original risk assessment was developed based on CoC concentrations in the Shallow Zone groundwater. As additional data were collected from the Wilcox Formation, it became possible to determine whether the CoCs identified in the Shallow Zone are also CoCs in the Wilcox Formation. Therefore, the CoCs identified in the Shallow Zone groundwater were considered potential COCs in the Wilcox Formation. The Wilcox Formation results were screened against the MCLs and PCLs for the various CoCs. The results identified the CoCs in the Wilcox Formation. These CoCs include MC, TCE, perchlorate, 1,4-dioxane, cis-1,2-DCE, benzene, 1,1,2-TCA, VC, arsenic, and barium. PCE, 1,3,5-trinitrobenzene, and bromodichloromethane, have been retained on a provisional basis because of high detection limits for PCE and bromodichloromethane, and due to lack of recent data for 1,3,5-trinitrobenzene. 1,4-Dioxane has been added as a result of its detection in several wells across the site above the TRRP PCL.

The soil at LHAAP-18/24 presented a cancer risk of 5.0×10^{-7}, which is less than the acceptable cancer risk range of 1×10^{-6} to 1×10^{-4}, and a total HI of 0.042, less than the acceptable HI of 1. No CoCs were selected for soil based on human health considerations.

The Installation-Wide Baseline Ecological Risk Assessment (Final Installation-Wide BERA – Shaw, 2007b) did not identify potential risk to ecological receptors at LHAAP-18/24. Should there have been any ecological risk, it would have been expressed by this point in time. An addendum to the BERA was completed in 2014 (AGEISS, Inc., July 8, 2014). The conclusions of the 2007 BERA were not changed by the 2014 BERA Addendum.

Remedial Action Objectives

The Army recognizes the USEPA's policy to return all groundwater to potential beneficial uses, based on the non-binding programmatic expectation in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP). The Remedial Action Objectives (RAOs) for LHAAP-18/24, which address contamination associated with the media at the site and take into account the future uses of LHAAP streams, land, and groundwater are:

Groundwater:

- Prevent human exposure to the groundwater contaminated with volatile organic compounds (VOCs), metals, and perchlorate above cleanup levels
- Prevent or minimize contaminated groundwater from discharging to surface water above cleanup levels
- Prevent or minimize further migration of the contaminant plume
- Return groundwater to its potential beneficial uses as drinking water, where practicable.

Source Materials:

- Prevent or minimize further migration of contaminants from source materials in the saturated and unsaturated zones to groundwater.

Remedial Alternatives

This FS identifies and screens remedial technologies and associated process options that may be appropriate for satisfying the RAOs for LHAAP-18/24. Selected remedial technologies and process options were carried forward for further evaluation after the initial screening, and were combined to develop the following list of potential remedial alternatives for LHAAP-18/24:

- **Alternative 1 – No Action.** Contaminated groundwater and source areas in the saturated and unsaturated soil would be left in place with no remedial action or additional measures to prevent exposure to the CoCs or to prevent migration. The no action alternative serves as a baseline for comparison with other alternatives as required under CERCLA. The no action alternative does not meet the RAOs.
- **Alternative 2 –Enhanced Groundwater Extraction and Ex Situ Treatment, Land Use Control (LUC), Enhanced In Situ Bioremediation (ISB) Inside & Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal.** The existing groundwater extraction and treatment system would continue operating for

contaminant removal, hydraulic control, and groundwater treatment. However, interception collection trenches (ICTs), ICT3 and ICT9, previously inactivated, would be reactivated based on a material balance identifying these ICTs as critical for removing more contaminant mass from groundwater. Saturated soil contaminated with VOCs or perchlorate at high concentrations that may be acting as a source of groundwater contamination (one area in the UEP vicinity and another area in the ACD vicinity) would be remediated by enhancing groundwater extraction using vertical extraction wells. ISB would be conducted in shallow zone contaminated areas inside and outside the containment area and in three areas in the Wilcox Formation. Unsaturated soil in two areas south of the UEP and two areas to the west of the UEP would be excavated and disposed off-site. The cost estimate for two soil areas beneath the UEP will be developed and included in the FS but the actual implementation would be deferred to 2024 at the earliest. In the interim, maintenance of the UEP cap will continue. A new groundwater treatment plant (GWTP) enhanced with an advanced oxidation process for treatment of 1,4-dioxane is included in this alternative. This alternative would take a very long time (several hundred years) to achieve RAOs. LUCs would be implemented to prevent human exposure to contaminated groundwater.

- **Alternative 3 – Groundwater Extraction and Treatment, Monitored Natural Attenuation (MNA) Outside the Containment and in Wilcox Formation, LUC, and Containment.** A slurry wall would be used to contain the contaminated groundwater in the shallow zone; additional soil cover would be added to portions of the site and the drainage ditches would be improved to promote runoff and reduce infiltration. The slurry wall would be tied into the clay layer, where present, that separates the Shallow Zone from the Wilcox aquifer. Where the clay layer is not present, the slurry wall would be installed to a depth just below the bottom depth of Harrison Bayou to the north of the containment. The existing groundwater extraction system would be used as needed to maintain hydraulic control inside the slurry wall, and would be ramped down gradually to an approximate 65% extraction rate (actual rate that would be required to achieve an inward and upward gradient would be determined with a 2-year hydraulic evaluation). MNA would ensure that groundwater contamination remains localized for the areas outside the slurry wall and within the Wilcox Formation. This alternative would take a very long time (several hundred years) to achieve RAOs. A new GWTP is included in this alternative, which incorporates an advanced oxidation process for the treatment of 1,4-dioxane. LUCs would be implemented to prevent human exposure to contaminated groundwater. Maintenance of the UEP cap will continue.

- **Alternative 4 – Enhanced Groundwater Extraction and Treatment, LUC, Enhanced ISB Inside & Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, and Surfactant Enhanced DNAPL Removal.** Saturated soil contaminated with VOCs or perchlorate at high concentrations that may be acting as a source of groundwater contamination (one area in the UEP vicinity and another area in the ACD vicinity) would be treated via surfactant flushing. ISB will also be applied to these areas after completion of surfactant flushing as a polishing step because surfactant flushing effectiveness might be hindered by low permeability zones and to remove perchlorate which is not treated via surfactant flushing. ISB would be conducted in shallow zone contaminated areas inside and outside the containment area and in three areas in the Wilcox Formation. Unsaturated soil in two areas south of the UEP, two areas to the west of the UEP, and two areas beneath the UEP would be excavated and disposed off-site. The cost estimate for two

soil areas beneath the UEP will be developed and included in the FS but the actual implementation would be deferred to 2024 at the earliest. Maintenance of the UEP cap will continue. The groundwater extraction system in its enhanced form (reactivation of ICT 3 and ICT 9) would continue operating to maintain hydraulic control and remove remaining Shallow Zone contaminants within the containment area. A new GWTP enhanced with an advanced oxidation process for treatment of 1,4-dioxane is included in this alternative. This alternative would achieve site RAOs more quickly than Alternatives 2 and 3, but is expected to exceed 30 years. LUCs would be implemented to prevent human exposure to contaminated groundwater.

- **Alternative 5 – Enhanced Groundwater Extraction and Treatment, LUC, Enhanced ISB Inside and Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, Thermal DNAPL Removal.** This alternative is the same as Alternative 4 with the exception that thermal treatment is applied at the residual DNAPL source areas of the UEP and ACD instead of surfactant flushing. While the technology is more expensive, it is very effective in low permeability zones where the majority of the residual DNAPL resides. Removal rate of 99.9% is expected. ISB would be applied to the thermally-treated areas as a polishing step after thermal treatment is completed. It is estimated that this alternative allows achievement of the RAOs within 20 years.
- **Alternative 6 - Enhanced Groundwater Extraction and Treatment, LUC, Enhanced ISB Inside and Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, Enhanced DNAPL Remediation using Zero-Valent Iron (ZVI).** This alternative is the same as Alternative 5 but instead of use of in situ thermal remediation, zero-valent iron for treatment of residual DNAPL source areas will be used. Uniform distribution of zero-valent iron in low permeability zones may not be possible due to subsurface heterogeneity and therefore, effective remediation of these areas by ZVI may not be effective. Hence, ISB will be applied to these areas after ZVI remediation is completed as a polishing step. It is estimated that 70% to 80% reduction in CoCs will occur after each injection of ZVI with two injections planned for the site. With application of ISB after the ZVI, it is estimated that this alternative allows achievement of the RAOs within 30 years.

Each alternative was evaluated against CERCLA criteria to provide a basis for selecting a preferred alternative in the follow-on Proposed Plan (PP) and Record of Decision documents.

Table ES-1 summarizes the comparative analysis of the alternatives presented in this Revised FS. Two additional criteria, State acceptance and community acceptance, will be evaluated during the PP stage.

Table ES-1: Comparative Analysis of Alternatives

Criteria	No Action	Alternative 2 Enhanced Groundwater Extraction and Treatment, ISB Inside & Outside Containment and in Wilcox, Unsaturated Soil Excavation, LUC.	Alternative 3 Containment, Groundwater Extraction and Treatment, MNA, LUC	Alternative 4 Enhanced Groundwater Extraction and Treatment, ISB Inside & Outside Containment and in Wilcox, Unsaturated Soil Excavation, Enhanced DNAPL Removal by Surfactant Flushing, LUC	Alternative 5 Enhanced Groundwater Extraction and Treatment, ISB Inside & Outside Containment and in Wilcox, Unsaturated Soil Excavation, Enhanced DNAPL Removal by Thermal Treatment, LUC	Alternative 6 Enhanced Groundwater Extraction and Treatment, ISB Inside & Outside Containment and in Wilcox, Unsaturated Soil Excavation, Enhanced DNAPL Removal by Application of ZVI, LUC
Overall protection of human health and the environment	No protection. Does not achieve RAOs.	Achieves RAOs but over a very long time. Protection of human health and environment provided by in situ bioremediation, ex situ groundwater treatment, DNAPL source removal, and maintenance of LUC. LTM to verify progress and hydraulic containment.	Achieves RAO for protecting human health by preventing exposure to contaminated groundwater. RAO for restoration of groundwater within the slurry wall area is not achieved within a reasonable time. Protection of human health and environment provided by physical containment of groundwater, and maintenance of LUC. MNA to treat areas outside slurry well and in Wilcox Formation. LTM to verify progress and containment.	Achieves RAOs. Protection of human health and environment provided by in situ bioremediation, ex situ groundwater treatment, DNAPL source removal, and maintenance of LUC. LTM to verify progress and hydraulic containment.	Achieves RAOs. Protection of human health and environment provided by in situ bioremediation, ex situ groundwater treatment, DNAPL source removal, and maintenance of LUC. LTM to verify progress and hydraulic containment.	Achieves RAOs. Protection of human health and environment provided by in situ bioremediation, ex situ groundwater treatment, DNAPL source removal, and maintenance of LUC. LTM to verify progress and hydraulic containment.
Compliance with ARARs	No compliance with chemical-specific ARARs.	Complies with all ARARs.	Will require an ARAR waiver for groundwater inside the slurry wall.	Complies with all ARARs.	Complies with all ARARs.	Complies with all ARARs.
Long-term effectiveness and permanence	Is not effective at protection of human health and the environment and does not provide permanence.	Soil removal is a permanent remedy. In situ and ex situ groundwater treatment permanently removes or destroys contaminants. DNAPL source removal permanently removes contaminants though effectiveness is limited and progress slow. LUC would be effective and reliable so long as they are maintained and enforced.	Containment would be permanent and effective so long as the slurry wall and hydraulic control are maintained. LUC would be effective and reliable so long as they are maintained and enforced.	Soil removal is a permanent remedy. In situ and ex situ groundwater treatment permanently removes or destroys contaminants. DNAPL source removal permanently removes contaminants although small amounts of residual DNAPL would remain in low permeability zones. LUC would be effective and reliable so long as they are maintained and enforced.	Soil removal is a permanent remedy. In situ and ex situ groundwater treatment permanently removes or destroys contaminants. DNAPL source removal permanently removes contaminants. LUC would be effective and reliable so long as they are maintained and enforced.	Soil removal is a permanent remedy. In situ and ex situ groundwater treatment permanently removes or destroys contaminants. DNAPL source removal permanently removes contaminants although small amounts of residual DNAPL would remain in low permeability zones. LUC would be effective and reliable so long as they are maintained and enforced.
Reduction of toxicity, mobility, or volume through treatment	No reduction outside of natural processes.	Reduced toxicity, mobility, and volume through in situ treatment, DNAPL and soil removal, and operating groundwater treatment system.	Very limited reduction of toxicity and volume with no treatment of source areas. Reduced mobility within slurry wall.	Reduced toxicity, mobility, and volume through in situ treatment, DNAPL and soil removal, and operating groundwater treatment system.	Reduced toxicity, mobility, and volume through in situ treatment, DNAPL and soil removal, and operating groundwater treatment system.	Reduced toxicity, mobility, and volume through in situ treatment, DNAPL and soil removal, and operating groundwater treatment system.
Short-term effectiveness	No short-term impacts.	Greater potential for impacts to the community or LHAAP workers through off-site transportation of excavated soil. Release to environment can be controlled during construction. Some potential for impacts to workers during in situ treatment applications. Duration several hundred years.	Potential for impacts to the community through increased construction activity. Some potential for impacts to workers during construction of slurry wall. Outside slurry wall area CoC removal estimated ≤ 20 years. Duration inside containment > 500 years.	Greater potential for impacts to the community or LHAAP workers through off-site transportation of excavated soil. Release to environment can be controlled during construction. Some potential for impacts to workers during in situ treatment applications. Duration 30+ years.	Greater potential for impacts to the community or LHAAP workers through off-site transportation of excavated soil. Release to environment can be controlled during construction. Some potential for impacts to workers during in situ treatment applications. Duration ≤ 20 years.	Greater potential for impacts to the community or LHAAP workers through off-site transportation of excavated soil. Release to environment can be controlled during construction. Some potential for impacts to workers during in situ treatment applications. Duration ≤ 30 years.

Table ES-1: Comparative Analysis of Alternatives

Criteria	No Action	Alternative 2 Enhanced Groundwater Extraction and Treatment, ISB Inside & Outside Containment and in Wilcox, Unsaturated Soil Excavation, LUC.	Alternative 3 Containment, Groundwater Extraction and Treatment, MNA, LUC	Alternative 4 Enhanced Groundwater Extraction and Treatment, ISB Inside & Outside Containment and in Wilcox, Unsaturated Soil Excavation, Enhanced DNAPL Removal by Surfactant Flushing, LUC	Alternative 5 Enhanced Groundwater Extraction and Treatment, ISB Inside & Outside Containment and in Wilcox, Unsaturated Soil Excavation, Enhanced DNAPL Removal by Thermal Treatment, LUC	Alternative 6 Enhanced Groundwater Extraction and Treatment, ISB Inside & Outside Containment and in Wilcox, Unsaturated Soil Excavation, Enhanced DNAPL Removal by Application of ZVI, LUC
Implementability	Technically implementable; administratively unacceptable.	Soil excavation readily implemented with standard earthmoving equipment. In situ bioremediation is a commercially available treatment technology. Extraction and treatment of groundwater is already implemented at the site. The effectiveness of extraction on DNAPL source removal is limited and controlled by the dissolution rate of DNAPL.	Implementable, but uncertainty exists in the effectiveness of slurry wall containment. Uncertain overall duration and cleanup levels possibly not attainable inside slurry wall.	Soil excavation readily implemented with standard earthmoving equipment. In situ bioremediation is a commercially available treatment technology. Injection of surfactants uses similar tools as in situ bioremediation. Dual phase extraction is an established technology.	Soil excavation readily implemented with standard earthmoving equipment. In situ bioremediation is a commercially available treatment technology. Thermal treatment is a commercially available technology but planning well in advance is required.	Soil excavation readily implemented with standard earthmoving equipment. In situ bioremediation is a commercially available treatment technology. Injection of ZVI uses similar tools as in situ bioremediation.
***Costs**						
Capital	$0	$14,560,000	$6,410,000	$13,110,000	$19,520,000	$102,230,000
O&M	$0	$19,600,000	$12,240,000	$19,390,000	$13,150,000	$19,390,000
Total	$0	$34,160,000	$18,650,000	$32,500,000	$32,670,000	$121,620,000
State Acceptance	This criterion will be evaluated in the Proposed Plan after state agency comments are provided					
Community Acceptance	This criterion will be evaluated in the Proposed Plan after community comments are provided					

Notes and Abbreviations:

* Costs are net present value and have been rounded to the nearest $100,000.

ARAR	applicable or relevant and appropriate requirement	LUC	land use control
CoC	contaminant of concern	MNA	monitored natural attenuation
LHAAP	Longhorn Army Ammunition Plant	O&M	operation and maintenance
LTM	long-term monitoring	RAO	remedial action objective
ISB	in situ bioremediation		

1 INTRODUCTION

This Feasibility Study (FS) was prepared by AECOM Technical Services, Inc. (AECOM), for This Revised Feasibility Study (FS) was prepared by AECOM Technical Services, Inc. (AECOM), for the United States (U.S.) Army Corps of Engineers (USACE), Tulsa District, under the Huntsville District's Worldwide Environmental Remedial Services No. W912DY-09-D-0059 Task Order No. DS01, for remediation activities at the former Longhorn Army Ammunition Plant (LHAAP) located in Karnack, Texas. This FS presents the analysis of remediation alternatives for the Burning Ground No. 3 and the Unlined Evaporation Pond (UEP) (designated as LHAAP-18/24) in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA).

The U.S. Army Environmental Command provides funding for the environmental remedial activities at LHAAP. The Base Realignment and Closure Division is responsible for all aspects of LHAAP including the environmental program, operations, and land transfer.

1.1 Purpose and Organization of Report

Environmental cleanup decision making under CERCLA follows a prescribed sequence: Remedial Investigation (RI), FS, Proposed Plan (PP), and Record of Decision (ROD). The RI serves as the mechanism for collecting data to characterize site conditions, determining the nature and extent of the contamination, and assessing risks to human health and the environment from the contamination. This investigatory element of decision making for LHAAP-18/24 has been completed and documented in an RI report (Jacobs, 2001) and a baseline risk assessment report (Jacobs, 2002). However, additional investigations at the site were conducted for the U.S. Department of the Army (U.S. Army) by AECOM in 2013 and 2014 to collect post-screening investigation data deemed necessary to support a revision of the Draft Final FS for LHAAP-18/24 (Shaw, May 2010). The results of the 2013 and 2014 investigations are presented in the Updated PSI Report (AECOM, 2016a). Additionally, treatability testing of viable alternatives was completed as part of supplemental investigation work conducted in 2016. The results of these additional investigations and treatability testing are documented in a Supplemental to the Updated PSI Report (AECOM, 2016c), and various testing laboratory reports that are appended to this Revised FS.

The Revised FS takes the next step of identifying and evaluating remedial solutions to the environmental problems identified for LHAAP-18/24. This step begins by briefly summarizing the findings of the RI and risk assessment and by updating these findings based on subsequent sampling and analyses. Based on those findings and the resulting Conceptual Site Model (CSM), Remedial Action Objectives (RAOs) are defined for the site. Viable alternatives are then formulated by considering general response actions (GRAs), types, volumes, or areas of media to be addressed, treatability testing results, and potentially applicable technologies and process options. After a reasonable set of alternatives has been formulated, the alternatives undergo a detailed analysis using nine established evaluation criteria under CERCLA. The detailed analysis profiles individual alternatives against the criteria and compares them with each other to gauge their relative performance. Each alternative that makes it to this stage of the analysis, with the exception of the required "no action" alternative, is expected to be protective of human health and compliant with applicable or relevant and appropriate requirements (ARARs) (unless a

waiver is justified), which are threshold requirements under CERCLA. The alternatives developed in this Revised FS address the media and contaminants of concern (CoCs) at LHAAP-18/24 through combinations of source control and groundwater actions.

The main text of this Revised FS is composed of the following sections:

- Section 2, "Risk and Site Assessment," summarizes the risk assessment approach and conclusions. It also provides the CSM for LHAAP-18/24 and discusses the LHAAP-18/24 media contamination assessment. This section also includes the updated CSM and incorporates the findings from the 2013 and 2014 investigations documented in the Final Updated PSI Report (AECOM, 2016a).
- Section 3, "Remedial Action Objectives and Cleanup Levels," presents the RAOs and a discussion of cleanup levels. The chemical-, location- and action-specific ARARs are presented in this section.
- Section 4, "Identification and Screening of Technologies and Process Options," summarizes the rationale for selecting technologies and process options for remediation of contamination to meet the RAOs.
- Section 5, "Development and Description of Alternatives," presents the rationale for developing a range of alternatives as well as a description of each alternative.
- Section 6, "Detailed Analysis of Alternatives," evaluates, compares, and contrasts the benefits and costs of the alternatives.
- Section 7, "References," presents the references cited in this document.

This Revised FS also includes a number of appendices that support the main text. **Appendix A** presents an evaluation of natural attenuation (NA) of groundwater contaminants at LHAAP-18/24. **Appendix B** provides the Draft Final Supplemental to the Updated PSI Report (AECOM, 2016c) and **Appendix C** compiles the treatability study results. **Appendix D** presents the cost estimates for the remedial action alternatives.

The preferred alternative for LHAAP-18/24 will be presented in the PP. The PP will briefly summarize the alternatives studied in this Revised FS, highlighting the key factors that led to identifying the preferred alternative. The U.S. Army will submit the PP to the regulatory agencies, TCEQ and USEPA, and then the public for review. After this review, the U.S. Army will release a ROD that documents the selected remedy, certifies that the remedy selection process was carried out in accordance with CERCLA, and addresses public comments on the PP. Relevant documentation, including the RI, Revised FS, and subsequent documents, are or will be available to the public in the Administrative Record (AR) for this project. The AR is housed at LHAAP and at the Marshall Public Library in Marshall, Texas.

1.2 LHAAP Background

The LHAAP is an inactive, government-owned, formerly contractor-operated and maintained industrial facility located in central-east Texas in the northeastern corner of Harrison County. The facility currently occupies approximately 1,200 of its former 8,416 acres located between State Highway 43 in Karnack, Texas, and the western shore of Caddo Lake as shown in **Figure**

1-1. LHAAP was listed as a National Priorities List (NPL) site on August 9, 1990, due to threatened releases of hazardous substances, pollutants, or contaminants. The USEPA, the Texas Water Commission (now the TCEQ), and the U.S. Army signed a Federal Facility Agreement (FFA) on December 30, 1991.

The nearest cities are Marshall, Texas, approximately 14 miles to the southwest, and Shreveport, Louisiana, approximately 40 miles to the southeast. Caddo Lake, a large freshwater lake situated on the Texas-Louisiana border, bounds LHAAP to the north and east. The industries in the surrounding area consist of agriculture, timber, oil and natural gas production, and recreation.

1.3 LHAAP-18/24 Background

LHAAP-18/24 is a 34.5 acre fenced, cleared area (with an interim remedy that includes a containment area) located in the southeastern section of LHAAP (**Figure 1-2**). The site is located between Avenue Q to the southeast and Harrison Bayou to the northwest. LHAAP-17 (Burning Ground No. 2) is to the southwest (**Figures 1-2 and 1-3**), and heavily wooded areas lie to the east and northeast. The area had been used for the treatment, storage, and disposal (TSD) of solid and liquid explosive, pyrotechnic, and combustible solvent waste by open burning/open detonation, incineration, evaporation, and burial. LHAAP-18/24 encompasses a number of Defense Environmental Restoration Program Management Information System sites:

- Burning Ground No. 3;
- Rocket Motor Washout Pond;
- Former UEP;
- Burn Burial Area;
- 24-X Holding Area;
- 25-X Washout Pad;
- Air Curtain Destructor (ACD);
- Three Open Burning Cage;
- Two Open Burning Pan;
- Building 41-X; and
- Building 43-X.

The locations of these sites within LHAAP-18/24 are presented in the Environmental Site Assessment (Plexus, 2005) and identified in **Figure 1-3**. The former UEP/Rocket Motor Washout Facility is located within the northern corner of LHAAP-18/24.

LHAAP-18/24 is generally vegetated with grass and weeds and is crossed by a number of paved roads. It is situated on a natural topographic high slightly west of the crest of a small topographic divide between Harrison Bayou and Saunder's Branch. The topography of the site has been greatly altered by operations over the past 35 years. LHAAP-18/24 is mostly level, with more relief near the western corner that contained an ACD until 2003, and near the northern corner that contains the mounded surface of the former UEP.

Burning Ground No. 3 operated between 1955 and 1998. Historical waste management units include open burn pits, the UEP, stockpiles of solvent-soaked sawdust, and suspected waste burial pits. The UEP was constructed at the burning ground in 1963 as a holding pond to store explosive wastes resulting from the washout of rocket motor casings. In 1973, the pond also began receiving waste water containing solvent residues and solids. An ACD was built in 1979 for the purpose of disposing of explosive and explosive-contaminated wastes by burning.

Use of burn pits and trenches were reportedly discontinued in 1984, and the use of the UEP was discontinued in 1984 when it was discovered that the pond was contaminating groundwater beneath the site. The UEP was closed as a Resource Conservation and Recovery Act (RCRA) interim status surface impoundment in 1986 by removing the waste and capping the impoundment. The last burning cage was removed in 1998.

Wastes removed during the closure of the UEP were disposed off-site at a RCRA certified disposal facility. As part of the LHAAP-18/24 Interim Remedial Action (IRA), approximately 32,000 cubic yards of source area soil were excavated and treated by low temperature thermal desorption. Some of the treated soil was placed at LHAAP-12 and LHAAP-16.

A groundwater extraction system incorporating approximately 5,000 feet (ft) of interceptor collection trenches (ICTs) and a groundwater treatment plant (GWTP) was installed in 1997 to control the migration of contaminated groundwater. As of September 2014, approximately 120.5 million gallons of contaminated groundwater had been extracted and treated. The treated water is to be primarily released to Harrison Bayou with occasional releases to the INF Pond or as irrigation water on LHAAP-18/24. However, due to drought conditions since 2011, the majority of the water has been released as irrigation water due to low or no flow in Harrison Bayou.

Between 18 September 2007 and 13 October 2008, four major system modifications were implemented to optimize the interim remedy. These modifications were:

- Injection of GWTP effluent into the shallow groundwater via two former ICTs 6 and 9,
- Conversion of monitoring well 18WW17 to an extraction well,
- Deactivation of ICTs 1, 3, 5, 10 and 12A, and
- Implementation of extraction at EW-1.

Reinjection into ICTs 6 and 9 was discontinued in July 2012. ICT 12A was reactivated in December 2012 and extraction from EW-1 was continued.

1.4 Surface Water Hydrology

Harrison Bayou flows within approximately 200 ft of the western corner of LHAAP-18/24. There are no surface water bodies or watercourses running through the site, however, minor drainage paths have been observed in the northwestern part of the site, associated with intermittent ponding in low areas after heavy rainfall events. Surface drainage occurs in all directions, but flow is generally directed toward Harrison Bayou to the west and by both natural and manmade ditches and drainage swales to the north. Harrison Bayou drains into Caddo Lake,

which is located approximately one mile northeast of LHAAP-18/24. The extreme western corner of the site is located within the 100-year floodplain of Harrison Bayou.

1.5 Hydrogeology

Figure 1-4 shows the locations of monitoring wells and soil, sediment, and surface water sampling locations at LHAAP-18/24, prior to the PSI. Until recently, the existing CSM (i.e., through June 2012) described three groundwater zones that were identified jointly by the FFA parties for LHAAP-18/24: shallow, intermediate, and deep. The three groundwater zones were described as somewhat separated by non-uniform, non-contiguous clay or silty clay layers. The separation between aquifer zones was, therefore, primarily descriptive and defined by the intervals in which groups of monitoring wells had been completed. The depth of monitoring wells in the shallow groundwater zone was indicated to occur between 10 and 53 ft below ground surface (bgs). The depth of monitoring wells in the intermediate groundwater zone was indicated to occur between 44 and 80 ft bgs. The depth of monitoring wells in the deep groundwater zone was described to occur between 98 and 185 ft bgs.

The CSM was updated on October 18, 2012, before completion of the 2013, 2014, and 2016 investigation activities, and was refined after completion of PSI data collection using a sequence stratigraphy methodology. The updated CSM describes the presence of only two groundwater zones at LHAAP-18/24: a "shallow zone" extending from the surface to a depth of approximately 45 ft bgs, and the Wilcox Formation below the shallow zone. Generally, these two units are separated by a contiguous clay layer which is believed to be present across the entire site with the exception of the area to the west and northwest towards Harrison Bayou (i.e., within the floodplain of Harrison Bayou) (**Figure 1-5**). As an example, it appears that the shallow zone and Wilcox Formation are well separated by the clay layer beyond the eastern edge of the site (e.g., near 18WW17 and 18WW18), while there is no separation (clay layer absent) just beyond the western corner (i.e., in the vicinity of 18WW02 and 18WW06). Between, these two areas, the clay layer beneath the shallow zone varies considerably in depth and thickness. Generally, based on the updated CSM, the wells previously described as "shallow" and "shallow/intermediate" are located in the shallow zone (up to a depth of 45 ft bgs), and those previously described as "intermediate" and "deep" wells are located in the Wilcox Formation (below 45 to 50 ft bgs). The updated CSM, including cross-sections identifying lithology at the site, is presented in the Final Updated PSI Report (AECOM, 2016a).

Figure 1-6 depicts the shallow groundwater elevations observed in June 2016, indicating the groundwater in the shallow zone flows radially outward in a complex pattern from the site. Shallow groundwater flow in the northwest area of the site is towards Harrison Bayou. To prevent discharge of groundwater to surface water, the interim remedial action was implemented in 1997. Localized influence of groundwater extraction can be observed in the shallow aquifer. The potentiometric map for the Wilcox Formation for June 2016 (**Figure 1-7**) indicates that the gradient and direction of flow in the northern portion of the site to be similar to the shallow zone; toward Harrison Bayou. The groundwater flow pattern and gradient direction in the Wilcox Formation prior to installation of the groundwater extraction system was similar to what is observed today. **Figure 1-8** presents the shallow groundwater potentiometric map for November 1992, prior to installation of the extraction system.

Groundwater in the Wilcox Formation near LHAAP is currently used as a drinking water source.

As of May 2015, six active water supply wells near the LHAAP were identified (**Figure 1-2**). All these public water supply wells are located greater than two miles from LHAAP-18/24. Karnack Water Supply Corporation operates two groundwater supply wells servicing the town of Karnack. These wells were completed in 1905 to depths of 287 and 285 feet bgs and are located hydraulically upgradient approximately one-quarter mile northwest and one-half mile southwest of the town center, respectively. Caddo Lake Water Supply Corporation operates three groundwater supply wells located north and northwest of LHAAP that have been in use since 1905. These wells are hydraulically upgradient of LHAAP (Jacobs, 2002) with completion depths of 244, 185 and 310 feet below ground surface. Caddo Lake State Park operates one groundwater supply well located northwest and also upgradient of LHAAP-18/24. This well was installed in 1905 with a total depth of 292 feet. Due to the large distance between these wells and LHAAP, water removal from these wells is not expected to affect groundwater flow at the site. In addition, there are several livestock and domestic wells located in the vicinity of LHAAP with depths averaging 250 ft (**Figure 1-2**). There are three water supply wells located within LHAAP (see **Figure 1-2**), upgradient of LHAAP-18/24. These water wells supply water to buildings currently in use on the installation. Their approximate locations and depths are as follows:

- 150 ft south-southeast of the fire station, approximately 2 miles from LHAAP-18/24; 128 ft deep
- ½ mile southwest of the fire station, approximately 2 miles from LHAAP-18/24; 195 ft deep
- At the U.S. Fish and Wildlife Service facility, approximately 2.6 miles from LHAAP-18/24; 220 ft deep

All of these wells are at least 2 miles from LHAAP-18/24, and none of these wells are used for drinking water. Two additional wells that had previously supplied water to the installation have been plugged and abandoned. None of the water supply wells are associated with or are in imminent danger from the localized contaminated groundwater at LHAAP-18/24. The water well search report is presented in the Final Updated PSI (AECOM, 2016a).

1.6 Previous Investigations at LHAAP-18/24

The environmental media (e.g., soil, groundwater, surface water, and sediment) at LHAAP-18/24 have been the subject of numerous investigations to identify potential contamination. Those investigations are summarized in **Table 1-1**. These include the Pre-RI investigations in 1980 (U.S. Army Environmental Hygiene Agency), in 1982 and 1987 (Environmental Protection Systems), and in 1986 (Camp, Dresser, & McKee). Phase I, Phase II, and Phase III RIs were conducted in 1993, 1995, and 1998, respectively (Jacobs Engineering Group, Inc.). The site-wide perchlorate investigation was conducted in 2002 (Solutions to Environmental Problems, Inc., 2005). An additional monitoring well, 18WW21, was installed in 2004 (Shaw, 2007a). Reports that document the studies mentioned above are included in the AR for LHAAP. A limited investigation for the presence of CoCs in unsaturated soil was performed in 2008 utilizing direct push technology (DPT) (Shaw, 2008).

The monitoring wells at LHAAP-18/24 have been periodically sampled to monitor the configuration of the contaminant plumes and to ensure that hydraulic containment is effective.

Results from the investigation completed in the Spring of 2013 and Spring of 2014 are presented in the Final Updated PSI Report (AECOM, 2016a) and the results of the spring of 2016 investigation is presented in the Draft Final Supplemental to the Updated PSI Report (AECOM, 2016c) (**Appendix B**). **Figures 1-9** through **Figure 1-16** present the isopleth maps for perchlorate, trichloroethene (TCE), methylene chloride (MC), and 1,4-dioxane from the June 2016 sampling event for the shallow zone and the Wilcox Formation, respectively. **Figures 1-17 and 1-18** present the metals concentrations for the metals that exceeded their respective maximum contaminant levels (MCLs) or Texas Risk Reduction Program (TRRP) Residential Groundwater Protective Concentration Limits (PCLs) for metals that don't have MCLs in the shallow zone and the Wilcox Formation, respectively.

A pilot study was implemented in July 2007 "to improve the performance of the containment area at LHAAP-18/24" (Shaw, 2007c). The major changes resulting from the pilot study are presented in **Section 1.3**. Two of those changes have been reversed as of July 2012, when reinjection of treated groundwater into ICT6 and ICT9 was discontinued and ICT-12A was reactivated.

A preliminary assessment of NA was prepared at LHAAP-18/24 (Shaw, 2010). The assessment was not based on geochemical or microbial data; rather, the long history of groundwater monitoring at LHAAP-18/24 provided the information to assess NA at LHAAP-18/24. Limited biogeochemical data was collected in 2013 from three wells during implementation of the PSI for NA evaluation. This information is presented in the Final Updated PSI Report (AECOM, 2016a). Assessment of NA for LHAAP-18/24 is primarily based on concentration trends and presence of degradation daughter compounds. The NA assessment completed at the site (Shaw, 2010) is presented in **Appendix A**.

The sample locations from previous investigations performed at LHAAP-18/24, excluding the data collected in 2013, 2014, and 2016 PSIs, are presented in **Figure 1-4**.

1.7 Remedial Actions at LHAAP-18/24

In addition to the IRAs described above, several remedial actions have been conducted at LHAAP-18/24. These are summarized in **Table 1-2**.

The largest of these IRAs were the closure of the UEP in 1986 and the excavation, treatment and disposal of soil in 1997. The total soil volume excavated was limited by contractual rather than remediation concerns. Exact limits of excavation were not well documented, and depths were likely limited to between 5 and 10 ft bgs, although accounts of deeper soil removal to 16 ft bgs in some areas were obtained (personal communication, 2013 from Chris Edgmon, former URS employee, to Wendy Lanier, USACE). Source areas identified in previous investigations and approximate limits of excavation are shown on **Figure 1-19**. This figure formed the basis for identification of potential remaining source areas used in implementation of the PSI and PSI Addendum activities (AECOM, 2016a), which collected data to identify areas that may require remediation.

Additionally, IRA implementation included installation of approximately 5,000 ft of ICTs and a GWTP for the extraction and treatment of groundwater at LHAAP-18/24. **Table 1-3** presents the physical characteristics of the ICTs. The groundwater extraction and treatment continues to date.

1.8 Potential Soil Source Areas

Using information from historical reports identifying potential unsaturated soil source areas and information from the IRA identifying areas of soil excavation, **Figure 1-20** was developed to identify the potential remaining vadose zone source areas. To develop the figure, all historical sampling results including soil vapor gas survey data, soil sample analytical results, and field-reported hydrocarbon concentrations (photoionization detector [PID], membrane interface probe, etc.) were used to develop the base map identified as **Figure 1-19**. All samples within the vadose zone collected in areas subsequently excavated during the IRA were then removed as depicted in the blue areas in **Figure 1-20**. Additionally, vadose zone concentrations meeting the following criteria were excluded as potential source areas:

- Volatile organic compounds (VOCs) in soil less than 500 micrograms per kilogram (µg/kg) and perchlorate less than 7,200 µg/kg (based on groundwater protection-industrial (GWP-Ind) MSC values for VOCs and perchlorate)
- PID less than 3 parts per million by volume (ppmv), which is considered a background concentration
- Soil gas survey detections less than 1 microgram per liter (µg/L) that were not substantiated by presence of soil contamination (i.e., the soil gas source is contaminated groundwater).

Additionally, soil data collected from saturated soils were excluded. Saturation of soils was determined based on depth to groundwater from adjacent monitoring wells. Generally, the depth to groundwater at LHAAP-18/24 is approximately 15 ft bgs but varies between a few ft bgs near Harrison Bayou to approximately 25 ft bgs in central areas of the site. The historical groundwater highs were used to determine the level of saturation (i.e., the zone of groundwater fluctuation is considered part of the saturated zone). **Figure 1-20** identifies those locations which could potentially represent remaining source areas and will be included in this Revised FS.

According to **Figure 1-20**, the remaining source areas include the areas immediately to the west and south of the former ACD, which were not excavated as part of the IRA, to the south of the former UEP (LHAAP-24), to the west of the former UEP, and beneath the UEP. Some of these locations were investigated in 2013 and 2014 and the locations exceeding the above criteria from these investigations are superimposed on the figure. These areas are further discussed below to identify which are of concern as a source of contaminants to groundwater and which remedial action might be employed.

- **Area West of ACD:** This area is located west of the IRA excavation area. Investigation indicated the presence of TCE, primarily, but MC was also observed at one location (18CPT27) and perchlorate at another location (18CPT09). Other than the soil gas results (samples SG-01, SG-07, and SG-55), the soil data with elevated TCE and MC were collected from soil samples at a depth of 7 to 10 ft bgs (8A-899, 8A-903, 18CPT27, and 18SB07). After further evaluation of groundwater levels in this area of the site (inside and outside of the containment area), it was determined that the maximum groundwater level inside the

containment in monitoring wells 120 and AWD-1 ranged between 3.41 and 6.25 ft bgs. Therefore, the impacted soil in this area of the site at this depth is within the range of natural groundwater table fluctuations, considering seasonal variations and potential intermittent influences from irrigation at the site. Similarly, perchlorate at 18CPT09 outside the containment area at a depth of 6 to 7 ft bgs is well within the saturated zone high as depicted by MW-16 and C-02 (these impacts were initially thought as being within the vadose zone as discussed in the PSI report). The maximum groundwater elevations at these wells were 3.18 and 0.58 ft bgs, respectively. Therefore, the impacted soil in this area at this depth is within the saturated zone and will not be considered in the remedial action for impacted soils, but will be addressed as part of impacted groundwater.

- **Area South of ACD:** This area is located south of the IRA excavation area. Three of the five locations identified in **Figure 1-20** are based on PID readings (SB-01, SB-02, and SB-03), with a fourth location based on soil gas data (SG-15). Only one boring had analytical concentrations reported (18SB06). TCE in this boring exceeded the TCE GWP-Ind MSC with 915 µg/kg at 10-12 ft bgs, but concentrations decreased to 447 µg/kg at a depth of 16 to 17 ft bgs. The highest groundwater table in this area ranged between 20.6 and 22.1 ft bgs based on data from AWD-3 and 129, respectively. This indicates that these samples are collected from the unsaturated soil. However, the results also indicate contaminant concentrations decrease with depth as a result of attenuation occurring in the soil due to volatilization losses, adsorption to the soil, and biodegradation. A similar observation is made for PID data from boring SB-02 where the PID response decreases with depth from 230 ppmv at 4 to 6 ft bgs to 7.6 ppmv at greater than 12.5 ft bgs. Therefore, the soil in this area of the site does not appear to be a source of contaminants to groundwater and will not be considered for remedial action.
- **Area South of UEP:** This area is composed of two areas, which were both excavated to 4 ft bgs, but TCE and MC occur at depths greater than 4 ft bgs at these locations. TCE concentrations greater than 500 µg/kg occur between 5.5 and 12 ft bgs (samples 8A-975, 8A-911, and 18SB02). The soil gas concentration for TCE at SG-39 at 4.5 ft bgs was very high at 430 µg/L, indicating a potential source of TCE in this area. The maximum groundwater elevation is approximately 19 ft bgs in MW-2 and MW-22, which bracket this area of the site. The investigation completed in 2014 in this area of the site identified one location at 18CPTPB17 with a TCE concentration of 531 µg/kg at a depth of 16 to 17 ft bgs. This concentration of TCE is very close to the GWP-Ind value of 500 µg/kg and is not of a major concern. The highest TCE concentration in the soil was reported in 18SB02 at a depth of 10 to 12 ft bgs at 11,800 µg/kg. The groundwater TCE concentration exceeds 10,000 µg/L; therefore, soil contribution to groundwater TCE concentrations is not significant at this time. Similarly, the MC concentration reported in 8A-911 at a depth of 8 ft was 4,318 µg/kg. The MC concentration in groundwater in this area is greater than 1,000 µg/L; therefore, the contribution of MC from soil to groundwater is not significant at this time. The TCE and MC contribution of soil to groundwater in this area could become relevant when the groundwater is remediated to concentrations less than those values. The soil in this area of the site will be considered as part of the remedial action.
- **Area Beneath the Former UEP:** The groundwater high beneath the UEP is at approximately 26.5 ft bgs. This area has been remediated to a certain depth. Remediation

information indicates that the native soil was not excavated during UEP closure, leaving potential source materials in the unsaturated soil; however, no data were collected during closure activities of the UEP. TCE is the primary CoC in this area, although tetrachloroethene (PCE) and MC are reported exceeding the GWP-Ind standard. TCE in 18CPT21 collected in 2013 was reported at 11,600 µg/kg at a depth of 16 to 17 ft bgs, which is 10 ft above the highest known groundwater elevation (i.e., at approximately at 26 ft bgs based on high groundwater elevation in MW-2 of 19 ft bgs in addition to UEP elevation of approximately 7 ft above native ground elevation). TCE in groundwater at this location was reported at 11,700 µg/L from a discrete groundwater sample. This concentration falls within the isoconcentration lines in this area of the site. The saturated and unsaturated soils at this location contained TCE at similar concentrations; therefore, based on saturated soil and groundwater TCE concentrations, the shallow unsaturated soil concentration of TCE is not a significant contributor to groundwater impacts at this time. The result of the sample collected at 18CPTUEP05 in 2014 indicated the presence of high MC in the soil at a depth of 24 to 25 ft bgs. The UEP cap is designed to minimize infiltration of rainwater; therefore, there is a low potential for TCE or MC in the unsaturated soil to leach to groundwater. Nonetheless, the TCE and MC-impacted soil at this location will be considered as part of the remedial action.

- **Area Beneath the Former UEP:** The groundwater high beneath the UEP is at approximately 26.5 ft bgs. 18CPT25 contained 7,960 µg/kg TCE at a depth of 15 to 16 ft bgs and 7,670 µg/kg at a depth of 21 to 22 ft bgs. Although a discrete groundwater sample collected at a depth of 28 to 32 ft bgs had a TCE concentration of 77.6 µg/L, the concentration in the discrete saturated soil sample collected at a depth of 31 to 32 ft bgs was 13,000 µg/kg TCE. The UEP cap is designed to minimize infiltration of rainwater; therefore, there is a low potential for TCE in the unsaturated soil to leach to groundwater. Nonetheless, TCE-impacted soil at this location will be considered as part of the remedial action.
- **Area to the West of the Former UEP:** Historical samples within the former Burn Burial area (8A-940 and 8A-984) to the west of the former UEP indicated the potential presence of TCE and MC soil sources at a depth of up to 14 ft bgs. Initially, these samples were not considered further as they appeared to be located within the former excavation depth of 16 ft bgs. However, to confirm that these exceedance soil areas were excavated, two soil borings 18CPTBB01 and 18CPTBB02 were driven in 2014 in the vicinity of borings 8A-940 and 8A-984 and soil samples collected at depths of 4.5 to 5.5 ft bgs, 22 to 23 ft bgs, 37 to 38 ft bgs, and 44 to 45 ft bgs for 18CPTBB01 and at 4.5 to 5.5 ft bgs, 15 to 16 ft bgs, 31 to 32 ft bgs, 39 to 40 ft bgs, and 47 to 48 ft bgs for 18CPTBB02 (Final Updated PSI Report, 2016). Only one sample at 18CPTBB02 at a depth of 4.5 to 5.5 ft bgs had a perchlorate concentration exceeding the GWP-Ind concentration of 7,200 µg/kg. No MC or TCE soil sources were identified in the unsaturated soil at these locations. Additionally, the nearest monitoring wells to these borings are AWD-2 and 123 with water level highs of 5.05 ft bgs and 3.81 ft bgs, respectively. The expected depth to groundwater at the boring locations located to the east of AWD-2 is slightly deeper or greater than 5 ft bgs. Therefore, the impacted soil at 4 ft bgs at 8A-940 and at 4.5 to 5.5 ft bgs at 18CPTBB02 is considered a threat to groundwater and will be targeted for remediation. Deeper soil samples at 8A-940 (e.g., at 10 ft bgs with TCE and MC exceedances) were not considered soil sources because these samples are located within the saturated zone. TCE was also detected in 18SB04 collected in August 2011 (i.e., after soil excavation had taken place) at depths of 10 to 12 ft bgs and 13 to 14 ft bgs. The depth to

groundwater high at this location is uncertain but is likely between 10 and 15 ft bgs. Therefore, the soil at this location could be a source of TCE to groundwater and will be targeted for remediation to a depth of 14 ft bgs.

In addition to the potential soil source areas discussed above, an area to the south of the site leading to the area in the vicinity of 18CPTMW22 outside the containment area was investigated in 2016 for the potential presence of a perchlorate source and for determining the extent of CoCs west of LHAAP-18/24 toward LHAAP-17 (Appendix B). Seventeen soil borings were driven to the Wilcox clay and soil samples were collected at approximately five-foot intervals and analyzed for perchlorate and VOCs. The results indicated that there is no perchlorate source in the soil or Shallow Zone groundwater and the presence of perchlorate in the vicinity of the former monitoring well 18CPTMW22 is likely historical migration to this area of the site. In addition to the 17 soil borings, four monitoring wells were installed in this area of the site. Monitoring well 18CPTMW22R was installed as a replacement of plugged and abandoned well 18CPTMW22 intended for the Shallow Zone (the well is actually screened in a perched unit above the Shallow Zone groundwater surface) ; monitoring well 18CPTMW22DW was used to determine the vertical extent of perchlorate in the Wilcox Formation; and monitoring wells 18CPTMW26 (Shallow Zone) and 18CPTMW26SW (upper Wilcox Formation) were installed to determine the extent of perchlorate in this area of the site in the direction of LHAAP-17. Very low concentrations of perchlorate (0.917 μg/L in 18CPTMW22R and 0.473 J μg/L in 18CPTMW22DW) and nondetect VOCs and 1,4-dioxane were reported in 18CPTMW22R and 18CPTMW22DW, defining the maximum vertical extent of the CoCs in groundwater. Monitoring well 18CPTMW26 had insufficient water to collect groundwater samples. Perchlorate was reported at 6.42 μg/L in 18CPTMW26SW, but VOCs and 1,4-dioxane were not detected. This well provides lateral extent determination in the shallow Wilcox Formation.

Notes

1) All monitoring wells installed in 2013 and 2014 have nomenclature beginning with "18CPT" with the exception of 18WW22 and 18WW24 which were also installed in 2013 and 2014, respectively.
2) "SW" at the end of well nomenclature indicates a shallow Wilcox Formation monitoring well (i.e., to a depth of 70 feet bgs).
3) "DW" at the end of well nomenclature indicates a deep Wilcox Formation monitoring well (i.e., to a depth of 100 feet bgs).
4) Only values exceeding the MCL or PCL have been included.

Screening Criteria:
- VOCs in soil > 500 µg/kg
- Perchlorate in soil > 7,154 µg/kg
- PID > 3 ppmv
- Soil gas survey detections > 1 µg/L
- Exclude excavation areas
- Exclude location sourcing from groundwater
- Exclude soil gas survey not substantiated with nearby boring data

Table 1-1: Summary of Previous Investigations at LHAAP-18/24*

USACE Remedial Investigations	
Pre-Phase I (Jacobs, 2001)	
USAEHA, 1980	Thirteen monitoring wells were installed and sampled (BH-1 to BH-11, BH-21, BH-22)
EPS, 1982	Nine Monitoring Wells were installed (101, 102, 109, 120, 123-126, and 129)
	Twenty-two monitoring wells were sampled (BH-1 series and the 9 newly installed wells)
CDM, 1986	Ten monitoring wells were installed (C-01 through C-10)
	Groundwater samples were collected from C-01 through C-10 and 18 existing monitoring wells
EPS, 1987	Groundwater samples were collected from three existing monitoring wells (BH6, BH11, and 102)
LHAAP RI/FS WP Volume,1 General June 1992 (USACE Ft Worth District)	
• 1987 sampling of eight wells (101,102, 109, 120, 123, 124, 125, & 129) for explosives, VOCs, total organic compound (TOC), total organic halide, & total & dissolved metals • Completion and sampling of 47 shallow borings • Completion and geophysical logging of 4 deep borings • Installation & sampling of 12 shallow monitoring wells (MW-1 through MW-12) • Installation & sampling of 3 deeper monitoring wells (MW-13 through MW-15) • Slug testing of all 15 new wells • 1988 September Groundwater samples were collected & tested from 25 wells (C-2 through C-5, 109, 120, 123, 124, 125, 129, & fifteen new wells) • 1989 Installation of 8 shallow monitoring wells (MW-16 through MW-23) and 1 deeper monitoring well (C-4A) • 1989 Geophysical logging the deep well boring for C-4A • 1989 November Groundwater samples were collected from all existing wells	
Data Summary Report of Investigations Results from 1976 through 1992 for Burning Ground 3 & the UEP, May 1993	
• 1990 June and September groundwater samples were collected for testing at MW-1 through MW-15 • 1992 November, the COE sampled 41 of the 49 wells at the site ((MW-1 through MW-23, C-1 through C-10 (including C-4A) 102, 103, 109, 120, 124, 126, 129, 130, BH-6,) to obtain data necessary for evaluating IRA alternatives and monitor plume concentrations and migration.	
Phases I of the Remedial Investigation (Jacobs, 2001)	
Jacobs, Phase I, 1993	Eight surface water and eight sediment samples were collected (18SW01 to 18SW08 and 18SD01 to 18SD08)

IRA Phases I, II, and III Investigation (AWD/DOW Environmental Inc./Radian 1993- 1998)	
AWD Technologies IRA Phases I Report February 1994	• 1993-Four new monitoring wells were installed in the shallow saturated zone (AWD-1,-2, -3 & -4) and one extraction well (EW-1) • Soil samples for geotechnical data (Physical) and Chemical testing were collected for all five wells • Slug test were performed on the new wells • 1993 Groundwater samples were collected from all existing monitoring wells and new wells • 1993 Eight new soil borings (SB-1 through SB-8) were completed and sampled • 1993 Three test pits were dug and samples collected for Treatability tests • All new wells and borings were surveyed for state plane coordinates and elevations • Groundwater elevations were collected for all existing monitoring wells and five new wells
DOW Environmental, Inc. (DEI) (Formerly AWD Technologies, INC.) Pilot Study Report - Phase II March 1995	• June 1994 Groundwater sampling and testing of 48 monitoring wells and the vertical extraction well (VEW) designated EW -1 which was installed during the implementation of the Phase I work. • 1994 Installation of a horizontal extraction well (HEW) under the ACD with soil sampling during installation and groundwater sampling from HEW after installation • 1994 Completion of Thirteen Soil Borings (AWD-5 through AWD-17) to investigate possible source material locations (around the ACD, in pits and the UEP) and to obtain information for installation of the Pilot Study ICT sections, samples were collected for physical and chemical testing • October/November, 1994.Groundwater sampling and testing of 48 monitoring wells and EW -1 following the completion of the flow tests in July/August
Phases II of the Remedial Investigation (Jacobs, 2001)	
Jacobs, Phase II, 1995	Eight surface water and eight sediment samples were collected (18SW01 to 18SW08 and 18SD01 to 18SD08)
	Eighteen surface water and 18 sediment samples were collected (18SW09 to 18SW26 and 18SD09 to 18SD26)
	Twenty-five soil samples were collected from 25 soil borings (18SS01 to 18SS25)
	Five deep soil borings were completed (18SB01 to 18SB05) for stratigraphic information
	Eighteen monitoring wells were installed (18WW01 to 18WW11 and 18WW14 to 18WW20) and groundwater samples were collected from each new well
Phases III of the Remedial Investigation (Jacobs, 2001)	
Jacobs, Phase III, 1998	Three surface water and three sediment samples were collected (18SW27 to 18SW29 and 18SD27 to 18SD29)
	Groundwater samples were collected from three existing wells (MW-1, MW-02, and MW-14)

Radian (Formerly DEI) Cost & Performance Report April 1999
1998 Groundwater samples were collected & tested for all remaining monitoring wells and ICT sumps
Additional Investigations
Perchlorate Investigation (STEP, 2005)
Environmental Site Assessment (Plexus, 2005)
Data Gaps Investigation (Shaw, 2007)
Final Sumps Evaluation (Shaw, 2008)
Direct Push Groundwater Sampling at 12 locations.
Routine Sampling of Existing Groundwater Treatment System (Quarterly Reports, Shaw)
Post-Screening Investigation (AECOM, 2013)

* From Draft Final Feasibility Study, LHAAP-18/24, Burning Ground No. 3 and Unlined Evaporation Pond, Longhorn Army Ammunition Plant, Karnack, Texas

Table 1-2: Summary of Previous Remedial Actions at LHAAP-18/24*

Date	Remedial Action
1980	The ACD began operation in 1980 burning non-hazardous waste. It operated through 2003, when it was removed.
1984	The burn pits were sampled, and contaminated soil and ash were removed to a permitted facility. The pits were backfilled with clean soil and grassed (TWC, 1988).
1986	8,116 cy of mostly barium and heavy metals sludge from the UEP were stabilized with Portland cement, removed, and sent to a permitted landfill in Carlyss, Louisiana. The pond was then capped (Jacobs, 2001).
1995	Seven monitoring wells were abandoned during the Phase II Remedial Investigation activities (BH-3, BH-4, BH-7, BH-11, BH-22, 124, and MW-15).
1995	Sumps 114, 115, and 116 were removed and disposed off-site as hazardous waste (114) or on-site as non-hazardous waste (115 and 116).
1997	An IRA was implemented. That action consisted of two major elements: • 32,000 cy of source soil were excavated and treated by low temperature thermal desorption, then placed at LHAAP-16 and LHAAP-12 (Jacobs, 2001) • 5,000 linear ft of interception collection trenches were installed with a vertical liner along the northwest and northeast boundaries of LHAAP-18/24, and a GWTP was constructed across the road to the southeast (Jacobs, 2001).
1999	In February 1999, 68 cy (57 tons) of soil were removed around open burning cage LHAAP-22W (Unit No. 6). All open burning cages and pans were also removed at this time.
1998 to Present	The groundwater extraction system is operated to control migration of contaminated groundwater. The GWTP removes contaminants from the extracted groundwater and then releases the treated water either by direct discharge to Harrison Bayou, irrigation at LHAAP-18/24, discharge to a holding pond, or (more recently) injection into the shallow groundwater at LHAAP-18/24. The GWTP is comprised of metals precipitation, air stripping, catalytic oxidation, and a fluidized bed reactor for the treatment of perchlorate which was added in 2002. In July 2007, a six day reinjection test of treated groundwater to ICTs 6 and 9 was conducted and on September 18, 2007, reinjection of treated groundwater into ICTs 6 and 9 was implemented on a long-term basis. Injection of treated water into ICTs was discontinued in 2012. Irrigation of treated water on the site has continued when there is not enough flow in Harrison Bayou for the release of treated water.

Notes:
Sump elevation calculated by subtracting total depth from TOC elevation.
Design elevation interpolated to nearest foot from July 1996 ICT Design Sheets.
ICTs were installed in 1998.
Elevations are reported as feet above mean sea level.
Total depths are reported as feet below TOC.
ICT interceptor collection trench
TOC top of casing, measuring point for groundwater elevations

2 RISK AND SITE ASSESSMENT

This section summarizes the risk assessment approach, risk conclusions, media contamination evaluation, and cleanup levels for LHAAP-18/24. Information in this section is based on data obtained from the following references:

- Group 2 Sites RI (Jacobs, 2001)
- Group 2 Sites Baseline Human Health Risk Assessment Report (Jacobs, 2002)
- Environmental Site Assessment (Plexus, 2005)
- Groups 2 and 4 Groundwater Data Gaps Investigation (Shaw, 2007a)
- Installation-Wide Baseline Ecological Risk Assessment (BERA) (Shaw, 2007b)
- Final Updated PSI Report (AECOM, 2016a)
- 1,4-Dioxane Groundwater Sampling Methodology and Analytical Results for LHAAP-18/24 at Longhorn Army Ammunition Plant, Karnack, Texas (AECOM, 2016b)
- Draft Final Supplemental to the Updated PSI Report (AECOM, 2016c)
- Final BERA Addendum (AGEISS, 2014)

Group 2, as referenced in the documents listed above, was a collection of environmental sites at LHAAP that included LHAAP-18/24.

2.1 Human Health Risk Assessment

This summary is based on the conclusions presented in the Final Baseline Human Health and Screening Ecological Risk Assessment for the Group 2 Sites (Jacobs, 2002). The risk assessment presented the human health risks and hazards from soil and groundwater to a hypothetical future maintenance worker under an industrial scenario. For the risk assessment, soil and groundwater data were used to calculate the aggregate risk values, which were then compared to the USEPA target risk range of 1×10^{-4} to 1×10^{-6} for excess lifetime cancer risk (ELCR) and to a hazard index (HI) of 1 for non-cancer risks. This risk assessment did not include 1,4-dioxane as a CoC because it was not detected at the high detection limits achieved at the time the samples were analyzed.

2.1.1 Soil

For the hypothetical future maintenance worker's exposure to soil at LHAAP-18/24, the carcinogenic risk was determined to be 5.0×10^{-7}, which is less than the USEPA target risk range of 1×10^{-4} to 1×10^{-6} ELCR. The non-carcinogenic hazard was determined to be 0.042, which is less than the acceptable HI of 1. Therefore chemicals in soil at LHAAP-18/24 do not pose unacceptable carcinogenic risk or non-carcinogenic hazard to human health.

2.1.2 Groundwater

For the hypothetical future maintenance worker's exposure to the groundwater at LHAAP-18/24, the carcinogenic risk and non-carcinogenic hazard exceed the acceptable limits. The total carcinogenic risk from groundwater for a hypothetical future maintenance worker was

determined at 4.4×10^{-1}, with TCE and MC contributing 99.98% of the risk. The total HI was calculated at 3,200, with MC, TCE, and perchlorate contributing greater than 98% of the HI. The reason for the high cancer risk and hazard index calculated for the hypothetical maintenance worker was related to the unrealistic assumption that groundwater extracted from the site would be used by the maintenance worker for showering, during which dermal and inhalation exposure to the contaminants in groundwater would occur. Exposure of the hypothetical future maintenance worker to the Wilcox Formation groundwater was not previously assessed because the concentrations of CoCs in the Wilcox Formation are less than the concentrations in the Shallow Zone groundwater and the risk from exposure to the Wilcox Formation groundwater is lower than exposure to the Shallow Zone groundwater. Additionally, very limited data were available for the Wilcox Formation at the time the assessment was performed. While additional data have since been collected, the presence and extent of CoCs are much more limited in the Wilcox Formation compared to the Shallow Zone. Since groundwater is being restored to MCLs, or to TRRP PCLs for those CoCs without MCLs, the discussion of risk to a hypothetical future maintenance worker due to exposure to the Wilcox Formation groundwater is not required. However, a determination of CoC concentrations in the Wilcox Formation will be made.

Chemicals identified in the Shallow Zone groundwater based on the risk assessment (Jacobs, 2002) with a risk greater than 1×10^{-6} or a hazard quotient (HQ) greater than 0.1 are listed in **Table 2-1** and **Table 2-2**, respectively. For the purposes of this Revised FS, these lists were expanded to include groundwater chemicals detected in excess of their associated Safe Drinking Water Act (SDWA) MCLs or TRRP PCLs, although they were not specified in the risk assessment. The chemicals were evaluated to determine which should be retained as CoCs. The reasons for retaining or excluding chemicals as CoCs are also shown in **Table 2-1** and **Table 2-2**, and are discussed further in **Section 2.2.2**. The added constituents were based on frequency of detection of these constituents in multiple wells over several sampling events. **Table 2-3** provides a summary of these six compounds that were added based on their detection above the MCL/PCL since September 2012 (between September 2012 and June 2016).

2.2 Evaluation of Data Collected Since the Risk Assessment

The risk assessment was completed using data from samples collected through February 2001 for groundwater and through 1998 for soil. Since that time, additional groundwater and soil samples have been collected and analyzed.

2.2.1 Soil

Additional soil samples were collected during the perchlorate investigation in 2002 (Solutions To Environmental Problems, Inc., STEP, 2005). These samples were analyzed only for perchlorate, and the results were all less than the GWP-Ind MSC of 7,200 µg/kg.

Three additional surface soil samples were collected in April 2006 for the installation-wide BERA (Shaw, 2007b). These samples were analyzed for total and hexavalent chromium, and results compared to TCEQ risk-based screening values. All results were found to be less than the soil MSC for industrial use based on inhalation, ingestion, and dermal contact (SAI-Ind).

Eight additional soil samples were collected in September 2006 for the sumps investigation (Shaw, 2008). The samples were analyzed for explosives, metals, semivolatile organic compounds (SVOCs), and VOCs. The results were all less than the SAI-Ind MSC values except

for vanadium, TCE, vinyl chloride (VC), and select SVOCs, which required further evaluation. In the sumps report, the additional sample results were used to calculate new exposure point concentrations (EPCs) analogous to the EPCs used in the human health risk assessment, and concluded that the new results would contribute negligible increases to the calculated cancer risk and non-cancer hazard values.

To address and identify remaining source areas, to conduct treatability studies, and to answer questions about vertical extent, PSI activities were conducted in 2013, 2014, and 2016. The 2013/2014 PSI studies resulted in collection of 271 discrete soil samples. Ninety five of these samples were collected from the unsaturated zone, 41 at the smear zone, and 135 from the saturated soil. For the unsaturated soil samples, the results were less than the GWP-Ind MSC values except for TCE in two samples (18CPT21 and 18CPT25), PCE in one sample (18CPT21), MC in two samples (18CPT21 and 18CPTUEP05), and perchlorate in one sample (18CPTBB02), which required further evaluation. Samples 18CPT21, 18CPT25, and 18CPTUEP05 were collected from within the former UEP and sample 18CPTBB02 was collected from former button bomb area to the west of the UEP.

The 2016 PSI study focused on the southern area of the site for perchlorate extent determination primarily in the Shallow Zone. One hundred and twenty one discrete soil samples were collected. Forty four of these samples were collected from the unsaturated Shallow Zone and 77 from the saturated soil in either the Shallow Zone, Wilcox clay, or Wilcox Formation below the Wilcox clay). For the unsaturated soil samples, the results were less than the GWP-Ind MSC values except for perchlorate in two samples (18DPT12 and 18CPTMW22DW), which required further evaluation. Sample 18DPT12 was collected from the Wilcox clay in the southern corner of the site just outside the containment. Sample 18CPTMW22DW was collected from the upper Wilcox Formation in the southern corner of the site just outside the containment. The 2016 Draft Final Supplemental to the Updated PSI Report is presented as **Appendix B**.

In general, the additional soil sample results do not change the conclusion of the risk assessments that soil poses no unacceptable human health risks to the hypothetical site worker.

2.2.2 Groundwater

Additional groundwater samples have been collected since the risk assessment and analyzed for perchlorate, metals, VOCs, SVOCs, and 1,4-dioxane. Proposed modifications to the CoCs are included in **Tables 2-1 and 2-2**. The reasoning for those modifications was discussed above. Six chemicals, (MC, TCE, chloroform, 2,3,7,8-tetrachlorodibenzo-p-dioxin [TCDD], bromodichloromethane, and 4,4'-dichlorodiphenyldichloroethane [DDD]) had a carcinogenic risk greater than 1×10^{-6}. Fourteen chemicals, (MC, TCE, perchlorate, chloroform, antimony, nickel, manganese, silver, barium, thallium, 1,3,5-trinitrobenzene, cis-1,2-dichloroethene, cobalt, and chromium) had an HQ greater than 0.1. Four organic chemicals that exceeded the MCL, PCE, benzene, 1,1,2-trichloroethane (TCA), and VC, and one that exceeded the PCL, 1,4-dioxane, were added to **Table 2-1** as CoCs. One inorganic that had exceeded the MCL, arsenic, and organic chemical that exceeded the PCL, 1,4-dioxane, were added to **Table 2-2** as CoCs. These chemicals were added based on their presence in groundwater at concentrations above the MCL/PCL in several wells.

The risks associated with 2,3,7,8-TCDD and 4,4'-DDD are less than 1×10^{-4} by at least one order of magnitude; therefore, these chemicals were not retained as CoCs. Individual risks associated

with chloroform and bromodichloromethane are also less than 1 x 10^{-4}. Originally, the MCL for total trihalomethanes of 80 µg/L was used for chloroform and dibromodichloromethane and historically, the results for monitoring well MW-2 exceeded the MCL of 80 µg/L. After dispute resolution between the USEPA and the US Army, the TRRP PCLs became the cleanup criteria for groundwater in absence of MCL. Therefore, the TRRP PCL for chloroform of 240 µg/L and for bromodichloromethane of 15 µg/L will be used. The maximum concentration of chloroform in June 2016 was reported below the PCL in MW-2. Therefore, due to its sporadic detection, chloroform is excluded as a CoC. However, because the detection limit for bromodichloromethane in MW-2 samples is higher than the PCL, it will be retained on a provisional basis, but will be evaluated for retention based on future groundwater results.

Antimony had relatively higher concentration results in samples from the early phase of the RI which skewed the EPC calculation. Subsequent RI sampling indicated much lower concentrations. Most recent results (e.g., June 2016) were all less than the MCL of 6 µg/L. The revised HQ using the recent maximum groundwater concentration, while not calculated in **Table 2-2**, is estimated at 0.036, which is less than 0.1. Therefore, antimony was excluded as a CoC.

Manganese had relatively higher concentration results in samples from the early phase of the RI which skewed the EPC calculation. Subsequent RI sampling indicated much lower concentrations, less than the EPC. A revised HQ for manganese was calculated by a ratio of maximum recent concentration to EPC giving a value of 1.1 (1.7×5,290/8,270), which is greater than 1.0. Although these concentrations are greater than the PCL of 1,100 µg/L, the concentrations are lower than the background 95% UTL for manganese of 7,820 µg/L. Therefore, manganese was not retained as a CoC.

Silver had an HQ value less than 1.0. Recent silver concentrations (e.g., June 2016) in groundwater were less than the detection limit of 1 µg/L, which is less than the PCL of 120 µg/L. The revised HQ based on recent maximum concentrations is significantly less than 0.1 (0.002). Silver was not retained as a CoC.

Barium had a HQ of 0.84 and June 2016 groundwater concentration indicated the presence of barium in several wells, with the maximum concentration exceeding the EPC and the MCL. Barium was retained as a CoC.

Thallium had an HQ value less than 1.0. Recent (e.g., June 2016) thallium concentrations in groundwater were less than the MCL of 2 µg/L. The revised HQ based on recent maximum concentrations is approximately 0.1. Thallium was not retained as a CoC on a provisional basis.

1,3,5-trinitrobenzene had an HQ value less than 1.0, but more than 0.1, with no recent analytical results. The EPC for 1,3,5-trinitrobenzene is greater than the PCL of 730 µg/L. Therefore, 1,3,5-trinitrobenzene was retained as a CoC on a provisional basis.

Cis-1,2-DCE had an HQ of 0.3 based on an EPC of 250 µg/L. The most recent groundwater results (June 2016) indicated the presence of cis-1,2-DCE at a concentration of 43,600 µg/L in MW-2. Therefore, cis-1,2-DCE is retained as a CoC.

Cobalt had an HQ value less than 1.0 at 0.14. The cobalt EPC and recent maximum concentrations (June 2016) are greater than the PCL of 240 µg/L. Although the revised HQ based on recent maximum concentrations is only 0.178, cobalt was retained as a CoC on a provisional basis due to the PCL exceedances.

Chromium had an HQ of 0.12 and June 2016 groundwater concentrations indicated the presence of chromium in several wells, with the maximum concentration exceeding the MCL. Therefore, chromium was retained as a CoC.

Nickel had an HQ of 4.7 and June 2016 groundwater concentrations indicated the presence of nickel in several wells, with the maximum concentration exceeding the PCL. Therefore, nickel was retained as a CoC.

Arsenic concentrations exceeding the MCL showed no correlation with site contamination. Conspicuously, some MCL exceedances occurred at monitoring wells far beyond the boundaries of the site, implying high background levels. Recent data from the June 2016 sampling event indicated the presence of arsenic exceeding the MCL in monitoring wells 126, 18CPTMW01SW, 18CPTMW18, 18CPTMW24, MW-16, MW19, and MW2. Nonetheless due to presence of arsenic in background areas, arsenic was retained as a CoC on a provisional basis.

The results obtained from these post risk assessment groundwater samples do not alter the conclusion of the risk assessment that groundwater poses risk to a hypothetical future maintenance worker.

2.3 Ecological Risk Assessment

The Final Installation-Wide BERA (Shaw, 2007b) evaluated potential hazards to ecological resources at LHAAP by conducting a screening evaluation to identify initial contaminants of potential ecological concern (COPECs) in the individual sub-areas and watersheds. The potential of these COPECs to adversely affect communities was evaluated for (1) organisms that have direct contact with the COPECs (e.g., plants and earthworms growing and living in contaminated soil); and (2) organisms that may be exposed to the chemicals via food chain pathways (e.g., ingestion of an earthworm living in the contaminated soil by a shrew). Potential impacts to invertebrate and plant communities were evaluated by comparing COPEC concentrations to benchmark values available from multiple literature sources. For the food chain exposure assessment, a number of measurement receptors were selected as representative species for the various trophic levels in the food web that could be at risk from contaminants in site media. The measurement receptors that were selected and used in the food chain evaluation included the following:

- Deer Mouse
- Raccoon
- Modified Raccoon (as a surrogate for the Louisiana Black Bear)
- Short-Tailed Shrew
- Red Fox
- Muskrat
- River Otter
- Townsend’s Big-Eared Bat
- Common Snapping Turtle

- Bank Swallow
- American Woodcock
- Belted Kingfisher
- Red-Tailed Hawk

A food chain model was developed and used to estimate the total dose for each measurement receptor based on species-specific considerations such as diet, body weight, ingestion rates, etc., using conservative exposure estimates. Ecological hazard estimates were developed based on exposure to all media, including soil in a particular sub-area and surface water and sediment from any watersheds present in the sub-areas. Two different soil depths were used for modeling exposure to ecological receptors: surface soil (0 to 0.5 foot) and total soil (0 to 3 ft). Each receptor was assumed to be exposed to one of the two depths based on its life history characteristics (e.g., burrowing animals were assumed to be exposed to total soil). Bioaccumulation of chemicals up the food chain was initially estimated using uptake factors obtained from available literature, and then refined using site-specific data obtained during the BERA.

Ecological effects quotients (EEQs) were developed for each of the measurement receptors. EEQs are similar to HQs for human health, and are calculated by dividing the total dose that the receptor is exposed to by the toxicity reference value (TRV), which is based on a no-observed adverse effect level (NOAEL) or the lowest-observed adverse effect level concentration. If the EEQ exceeds 1 for a receptor (based on the NOAEL TRV), then that chemical is considered to have a realistic potential to cause adverse ecological impacts, and is identified as a final COPEC that should be addressed either through remediation or further investigation. As discussed in the BERA, there are several important uncertainties associated with the assumptions used in the EEQ process, and it should be noted that EEQs greater than 1 do not necessarily mean that ecological impacts have occurred, or are occurring.

The Installation-Wide Baseline Ecological Risk Assessment did not identify potential risk to ecological receptors at LHAAP-18/24 (Shaw, 2007b). Should there have been any ecological risk, it would have been expressed by this point in time. The BERA Addendum completed in 2014 (AGEISS, Inc., July 8, 2014) did not change the conclusion of the 2007 BERA.

2.4 Media Contamination Assessment

Chemicals in the groundwater at LHAAP-18/24 pose an unacceptable risk to human health. Chemicals in soil do not directly pose an unacceptable risk to human or ecological receptors. Evaluation of data generated after the risk assessment did not identify any additional CoCs with risks exceeding the USEPA target risk level of 1×10^{-4}, or an HQ greater than 0.1, as shown on **Table 2-1** and **Table 2-2**. Although a limited number of CoCs were added to **Tables 2-1 and 2-2** based on maximum concentrations of recent results (e.g., June 2016), continued evaluation of those CoCs will be conducted based on their presence, distribution, and EPCs to determine their contribution to the risk posed by the site groundwater.

2.4.1 Soil

Based on the human health risk assessment, soil at LHAAP-18/24 poses no unacceptable carcinogenic risks or non-carcinogenic hazards to a hypothetical future maintenance worker at LHAAP under an industrial scenario.

As noted in **Section 2.3**, the Installation-Wide Baseline Ecological Risk Assessment did not identify potential risk to ecological receptors at LHAAP-18/24 (Shaw, 2007b). Should there have been any ecological risk, it would have been expressed by this point in time. The BERA Addendum completed in 2014 (AGEISS, Inc., July 8, 2014) did not change the conclusion of the 2007 BERA.

As discussed in **Section 1.8**, potential source areas in the soil that could impact groundwater are limited to the area to the south of UEP in the vicinity of 18SB02 and 8A-911 between 8 and 12 ft bgs and the in the vicinity of location 8A-975 between 5.5 and 12 ft bgs. These areas are located where soil excavation was conducted to a depth of 4 ft as part of the 1996 IRA. The data indicate the presence of potential source of CoCs to groundwater at these locations. The estimated extent of excavation conducted in 1996 at location 8A-911 was approximately 40 ft by 70 ft for a total area of 2,800 ft^2 and potential in-place total volume of 11,200 cubic feet (ft^3) or 414 cubic yard (yd^3). The estimated extent of excavation conducted in 1996 at location 8A-975 is approximately 50 ft by 50 ft for a total area of 2,500 ft^2 and potential in-place total volume of 16,250 ft^3 or 602 yd^3.

An area to the west of the former UEP in the area of the former Burn Burial was investigated in 2014 near former boring locations 8A-940 and 8A-984. The results indicated impacted soil at 4 ft bgs at 8A-940 (TCE and MC) and at 4.5 to 5.5 ft bgs at 18CPTBB02 (perchlorate) are considered a threat to groundwater. TCE was also detected in 18SB04 collected in August 2011 (i.e., after soil excavation had taken place) at depths of 10 to 12 ft bgs and 13 to 14 ft bgs.

Two areas beneath the UEP contain TCE above the GWP-Ind. These areas are in the vicinity of 18CPT21/18CPTUEP05/18CPT25 at a depth range of approximately 15 to 25 ft below the top of the UEP cover. While this soil does not pose a current threat to groundwater, because of the cap and the low TCE concentrations, it might pose a risk at some point in the future after groundwater VOC concentrations have been reduced to the MCL. Therefore, the remedial alternatives included in this Revised FS all include evaluation of the need for future remediation of the soil under the UEP cover.

2.4.2 Shallow Zone Groundwater

Based on the human health risk assessment, groundwater at LHAAP-18/24 poses an unacceptable carcinogenic risk and non-carcinogenic hazard to a hypothetical future maintenance worker at LHAAP under an industrial scenario.

Groundwater contaminants identified to have a cancer risk greater than 1×10^{-6} are listed in **Table 2-1**. The CoCs retained in **Table 2-1** for the LHAAP-18/24 groundwater are MC, TCE, PCE, benzene, 1,1,2-TCA, VC, and 1,4-dioxane due to their contribution to risk or exceedance of their respective MCL/PCL. Although none of the wells had historically detectable concentrations of bromodichloromethane, bromodichloromethane was retained on a provisional basis because the reporting limit for MW-2 exceeded the PCL due to dilution required for analysis. Should future groundwater compliance sampling events reveal that bromodichloromethane is not present in

groundwater at LHAAP-18/24 or concentrations are below the PCL, this CoC will be eliminated from further evaluation. Chloroform was not retained because its maximum concentration in MW-2 is below the PCL. The other two chemicals, 2,3,7,8-TCDD and 4,4'-DDD, were not retained as CoCs for the reasons noted in **Section 2.2.2**.

Groundwater contaminants with HQ's greater than 0.1 are listed in **Table 2-2**. Several CoCs have MCLs. For those chemicals without MCLs, the TRRP PCL was used for evaluation. The CoCs retained in **Table 2-2** for the LHAAP-18/24 groundwater are MC, TCE, perchlorate, cis-1,2-DCE, barium, chromium, nickel, and 1,4-dioxane due to the contribution to HI and/or exceedance of their respective MCL or PCL. 1,3,5-Trinitrobenzene, arsenic, and cobalt are retained on a provisional basis. Five chemicals (chloroform, antimony, manganese, silver, and thallium) were not retained as CoCs for the reasons noted in **Section 2.2.2**.

Thus, the current CoCs for groundwater at LHAAP-18/24 are VOCs (MC, TCE, cis-1,2-DCE, PCE, benzene, 1,1,2-TCA, VC, and 1,4-dioxane), metals (barium, chromium, and nickel), and the anion perchlorate. The following constituents were retained on a provisional basis: organics (1,3,5-trinitrobenzene and bromodichloromethane), and metals (arsenic and cobalt). Perchlorate, TCE, and MC present the vast majority of the human health risk in groundwater. **Figure 1-9** presents the most recent (June 2016) perchlorate concentrations in shallow zone groundwater. The area of groundwater contaminated with perchlorate exceeding the PCL is estimated at 67 acres. **Figures 1-11, 1-13, and 1-15** present the TCE, MC, and 1,4-dioxane concentrations in Shallow Zone groundwater using June 2016 data and **Figure 1-17** presents the metals exceedances in the Shallow Zone. Cis-1,2-DCE is not presented separately because the plume for cis-1,2-DCE is enveloped by the TCE plume. The other CoCs are present in sporadic locations, so plume maps for those CoCs have not been generated. The areas of groundwater contaminated with MC, TCE, and 1,4-dioxane are estimated at 7.3, 59, and 2.7 acres, respectively. The occurrences of other VOCs and metals concentrations in groundwater are intermittent and their distribution is generally not contiguous. In general, they do not present a clear pattern across the site.

The mass of dissolved-phase constituents in the Shallow Zone was estimated for perchlorate, TCE, MC, and 1,4-dioxane. The basis of this analysis was the groundwater concentrations detected in June 2016 and the isocontour lines depicted in **Figures 1-9, 1-11, 1-13**, and **1-15** for perchlorate, TCE, MC, and 1,4-dioxane, respectively. The areas between each set of adjacent isocontour lines were determined. Each of these areas was represented by the average isocontour line concentrations. For the inner-most isocontour line, the average of the concentration represented by the isocontour line and the concentration represented by the monitoring well(s) was calculated to represent the concentration for that area of the isocontour line. The average saturation thickness of groundwater in the Shallow Zone was calculated based on the difference between depth to the clay layer overlying the Wilcox Formation and the depth to groundwater measured in June 2016. **Table 2-4** presents the groundwater level calculations for this sampling event. The average groundwater saturation thickness was 11.96 ft, noting that this average would fluctuate with seasonal groundwater conditions. The results of mass estimates are presented in **Table 2-5**. The estimated dissolved phase mass for perchlorate was 7,950 lbs, 2,077 lbs for TCE, 419 lbs for MC, and 3.45 lbs for 1,4-dioxane. Note that the groundwater elevations used for these calculations are depressed due to groundwater extraction. Actual groundwater thickness could be greater by more than five (5) ft based on comparison of 1992 groundwater elevations

and June 2016 elevations. For every one (1) foot increase in groundwater table, the dissolved mass would increase by a factor of approximately 8.4%, assuming that groundwater concentrations remain unchanged. Additionally, if sorbed mass is present within the zone of groundwater fluctuations, an increase in groundwater elevation could increase the dissolved phase concentrations. Therefore, the dissolved phase mass could be substantially higher than the values shown in **Table 2-5**. However, for the purposes of this analysis, a groundwater average thickness of 11.96 ft is used.

2.4.2.1 Estimate of CoC Mass on Saturated Soil in the Shallow Zone

The mass of dissolved phase constituents in the shallow zone was used to estimate the mass adsorbed on the soil matrix for TCE and MC. The equation and parameters used to determine soil saturation concentrations are discussed in **Appendix F** of the Updated PSI Report for LHAAP-18/24 (AECOM, 2016a). The equation is taken from the Texas Risk Reduction Program (TRRP) guidance (TRRP Tier 2 PCL Equations, March 2000). The parameters are taken from site specific conditions (organic carbon, porosity, and bulk density) and from literature published values for solubilities and partition coefficients (TRRP, March 2016 lookup tables). **Table 2-6** presents these results for MC and TCE mass calculations in the soil. The estimated mass associated with the saturated soil for MC is estimated at 462 lbs and 3,647 lbs for TCE. A similar analysis was not done for perchlorate or 1,4-dioxane because perchlorate is a salt with complete solubility in water and 1,4-dioxane is miscible in water. The uncertainty associated with the dissolved mass estimation applies to estimation of CoC mass on the saturated soil.

2.4.2.2 DNAPL Analysis in the Shallow Zone

The concentrations of MC and TCE in groundwater in some portions of the site are sufficiently high to indicate the possible presence of dense nonaqueous phase liquid (DNAPL) within the saturated zone. As noted in *An Introduction to Characterizing Sites Contaminated with DNAPLs* (ITRC, 2003), "one indication of the presence of DNAPL in the saturated zone in a monitoring well with a long well screen (at least 10 ft long), is that the concentration of the contaminant is greater than one to ten percent (1-10%) of the compound's effective solubility." While this "rule of thumb" is not a conclusive indication of DNAPL, recent concentrations of MC and TCE shown below indicate the potential presence of DNAPL.

CoC	Solubility Limit [a] (µg/L)	Selected Concentrations at LHAAP-18/24 (µg/L)	% of solubility	Location	Saturated Screen Interval (feet)	Sampling Date
Methylene Chloride	15,400,000	1,050,000	6.8	MW-2	5	May 2013
		383,000	2.5	EW-1	20	February 2013
		173,000	1.1	ICT-12E	Trench	February 2013
Trichloroethene	1,100,000	68,400	6.2	MW-2	5	May 2013
		38,600	3.5	EW-1	20	February 2013
		97,400	8.9	ICT-12E	Trench	February 2013
		51,700	4.7	ICT-12D	Trench	February 2013
		24,500	2.2	120	15	May 2013
		14,400	1.3	MW-21	5	May 2013

Notes and Abbreviations:
a Source: TCEQ Texas Risk Reduction Program physical/chemical characteristics table (March 2016)
µg/L – micrograms per liter CoC – chemical of concern

As noted above, these concentrations are in excess of one percent (1%) and, historically, were sometimes in excess of ten percent (10%). While these CoC concentrations are not conclusive, they indicate that both MC and TCE were likely present as DNAPL in the past and are possibly still present as residual product in the saturated zone.

Soil sampling conducted in the spring of 2013 identified the potential presence of MC and TCE DNAPL at 18CPT21 between approximately 48 and 51 ft bgs and at 18CPT27 between approximately 23 and 35 ft bgs (see Appendix F of the Updated PSI Report (AECOM, 2016a) for estimation of soil concentrations above which DNAPL might be implied; and Appendix A of the same Report for membrane interface probe (MIP) logs indicating the presence of VOCs in the intervals indicated). 18CPT21 is located beneath the former UEP and 18CPT27 is located within the former ACD area. The determination of soil concentrations above which DNAPL would be implied is presented in the table below.

CoC	**TCE**		**MC**	
Parameter	**fine-grained soil**	**coarse-grained soil**	**fine-grained soil**	**coarse-grained soil**
Solubility (µg/L) [2]	1,100,000	1,100,000	15,400,000	15,400,000
Bulk Density (lb/ft^3)[1]	1.95	1.96	1.95	1.96
Porosity[1]	0.414	0.377	0.414	0.377
Organic carbon fraction[1]	0.001761	0.001871	0.001761	0.001871
OC-W Partition Coefficient (L/kg) [2]	93.33	93.33	11.75	11.75
Soil-Water Partition Coefficient (L/kg)[2]	0.1643	0.17461	0.0207	0.02198
Soil Saturation Limit (µg/kg soil)[3]	414,473	404,008	3,590,315	3,305,620

Further delineation of the potential presence of DNAPL was conducted between April and September 2014 in the former ACD and UEP areas. Cone penetrometer test (CPT)/MIP was driven at 11 locations surrounding 18CPT27 in the vicinity of the ACD area to determine the presence and potential extent of DNAPL in the saturated zone. A total of 46 discrete soil samples were collected from these locations and analyzed for VOCs and perchlorate. The results indicated the presence of DNAPL in another location (18CPTACD03) approximately 50 feet to the southwest of 18CPT27 and in the same general interval of approximately 23 and 35 ft bgs (TCE concentration was reported at 2,670,000 µg/kg in the sample at 26 to 28 ft bgs exceeding the theoretical solubility limit for TCE presented in the table above). **Figure 2-1** depicts the extent of DNAPL in the saturated zone in the former ACD area with the knowledge that there is no bright line between areas where DNAPL is present and areas where DNAPL is absent. The DNAPL impacted soil is characterized by fine-grained soil and described as the Wilcox clay. Therefore it appears that DNAPL has migrated into the fine-grained soil but none is observed in the overlying coarse-grained soil. This is likely the case because the site is mature and the extraction of groundwater in this area of the site resulted in the removal of the majority of DNAPL from the coarse-grained soils via physical extraction, but more likely via enhanced dissolution and volatilization.

The remainder of the 11 CPT/MIP data and analytical results did not indicate the potential presence of DNAPL, although relatively elevated concentrations of VOCs and perchlorate were observed. At eight (8) of the 10 locations (18CPTACD04, 18CPTACD05, 18CPTACD06, 18CPTACD07, 18CPTACD12, 18CPTACD13, 18CPTACD14, and 18CPTACD15) the high concentrations of VOCs and perchlorate were observed in the Wilcox clay with smaller amounts observed in coarse-grained soils. At only two locations (18CPTACD01 and 18CPTACD02) the elevated VOCs and perchlorate concentrations were observed in coarse-grained soils. 18CPTACD01 is the farthest location to the west and 18CPTACD02 is the farthest location to the north.

This information was introduced into the 14-compartment model developed by Sale and Newell and discussed in the ITRC document entitled: *Integrated DNAPL Site Strategy*, November 2011. The model provides a tool to aid in developing a simplified conceptualization of subsurface releases of chlorinated solvents. The model provides a complete view of the chlorinated solvent phases and their distribution in transmissive and low permeability zones within the source area and downgradient within the plume area. The 14 compartments of the model are shown in the table below along with qualitative estimates of the chemical potential in each compartment. The chemical potential refers to the relative amount of mass/concentration in each compartment relative to other compartments and allows for the determination of where the mass flux will occur (i.e., from which compartment to which other compartments). The information provided in the table below is taken from MIP and soil analytical results, analytical results of groundwater samples from AWD-1 located within the ACD area, and portioning information between the aqueous and soil per **Table 2-6** calculations.

14-Compartment Model Applied to ACD Area

Zone	Source		Plume	
	Lower K*	Transmissive*	Lower K	Transmissive
Vapor**	Low	Low	Low	Low
DNAPL	High	Low		
Aqueous	High	Moderate	Moderate	Moderate
Sorbed	High	Moderate	Moderate	Moderate

Notes and Abbreviations:

* Lower K refers to lower permeability zones or fine-grained soils that trap contaminants in the water and sorbed phases while the transmissive zone is the high permeability coarse-grained soils that allow advective transport of contaminants.
** In the saturated zone

The presence of DNAPL in the lower K zones but not in the transmissive coarse-grained zones has been documented and is indicative of a mature plume that has undergone extraction via the existing groundwater extraction system. It is expected that the aqueous and sorbed phases of VOCs to be high also in the lower K zones. The presence of VOCs in AWD-1 just outside the estimated DNAPL zone and monitoring well 120 downgradient from the source zone (i.e., in the plume zone) indicate the presence of moderate VOCs in the transmissive zones (assumed that the well data represent the transmissive zone more readily than the lower K zone). Because of the presence of moderate levels of VOCs in the transmissive zones, the sorbed phase is also considered moderate in these zones. Although lower K zones do not allow much if any advective

transport, the lower K zones in the plume would still contain moderate levels of CoCs via diffusive transport occurring over a long period of time associated with a mature plume.

The installation and operation of the groundwater extraction system occurred several decades after the occurrence of contaminant releases, allowing the DNAPL to migrate into the fine-grained soils. At the same time, the extraction system allowed removal of residual mass residing in the transmissive zones via direct recovery, but more likely via removal and depletion of aqueous-phase contaminants. The groundwater extraction system may have also accelerated migration of aqueous-phase contaminants from the source zones to the plume zones within the transmissive zone.

Based on this model, continued extraction of groundwater will continue to remove contaminant mass present in the transmissive zone and/or transported to the transmissive zone via diffusion from the lower K zones at the interphase between these zones. The presence of a source mass within the lower K zones will serve as a persistent source of groundwater contaminants. The groundwater extraction mass flux calculations are presented in **Section 2.4.2.6**. However, this model also indicates that removal of the source of contaminants within the lower K zones in the source area is required to reduce the lifecycle of the site. The presence of the majority of DNAPL/residual mass in lower K zones would hinder contaminant extraction or distribution of injected chemicals.

Further delineation of the potential presence of DNAPL in the UEP area was conducted between April and September 2014. CPT/MIP was driven at 18 locations surrounding 18CPT21 in the vicinity of the UEP area to determine the presence and potential extent of DNAPL in the saturated zone. A total of 80 discrete soil samples were collected from these locations and analyzed for VOCs and perchlorate. The results did not identify the potential presence of DNAPL in any location. Therefore, the depiction of DNAPL extent is governed by the results identified in 18CPT21 and the high concentration of MC in MW-2, implying presence of DNAPL in the vicinity of MW-2. **Figure 2-2** depicts the extent of DNAPL in the saturated zone within the UEP area. The DNAPL reported in 18CPT21 was identified in the fine-grained soil within the Wilcox clay.

At 18CPT21, the sample collected at 27 to 28 ft bgs from a coarse to fine-grained soil indicated the presence of high concentrations of VOCs (no perchlorate detected) but much lower (two orders of magnitude) than the concentrations at 48 to 49 ft bgs (Wilcox clay) where DNAPL was identified. Therefore it appears that DNAPL has migrated into the fine-grained soil but none is observed in the overlying coarse-grained soil. This is likely the case because the site is mature and the extraction of groundwater in this area of the site resulted in the removal of the majority of DNAPL from the coarse-grained soils via physical extraction and via enhanced dissolution and volatilization.

The results from the investigation conducted in 2014 indicated that the majority of the impact was identified in fine-grained soils within the saturated zone with eight (8) CPT/MIP locations (locations 18CPTUEP 04, 05, 06, 07, 10, 11, 12, and 17) out of 18 locations the soil was identified as Wilcox clay and at two (2) locations (CPT/MIP locations 18CPTUEP08 and 13) the contaminants resided primarily in fine-grained soil. Five (5) locations were characterized with little to no impact (CPT/MIP locations 18CPTUEP03, 09, 15, 16, and 17). Only at three locations the contaminants were identified in coarse-grained zones (CPT/MIP locations 18CPTUEP01, 02,

and 14). Therefore, it can be characterized that the majority of contaminants reside in fine-grained soil in the vicinity of the former UEP.

This information for the UEP area was introduced into the 14-compartment model. The 14 compartments of the model for the UEP area are shown in the table below along with qualitative estimates of the chemical potential in each compartment. The information provided in the table below is taken from MIP and soil analytical results, analytical results of groundwater samples from MW-2 located within the UEP area, and portioning information between the aqueous and soil per **Table 2-6** calculations. Based on the analytical data, the distribution of contaminants in the UEP area is similar to the distribution identified for the ACD area with the exception that the source concentration in the transmissive area was determined to be high based on the MC concentration in MW-2. The CSM for the UEP area is similar to the ACD area where the release has occurred decades ago before the extraction system was put in place and the effect of the extraction system is to decrease the transmissive zone concentrations particularly within the plume area. Also, a similar discussion about remedial technologies applies to this area as discussed for the ACD area.

14-Compartment Model Applied to UEP Area

Zone	Source		Plume	
	Lower K*	Transmissive*	Lower K	Transmissive
Vapor**	Low	Low	Low	Low
DNAPL	High	Low		
Aqueous	High	High	Moderate	Moderate
Sorbed	High	High	Moderate	Moderate

Notes and Abbreviations:

* Lower K refers to lower permeability zones or fine-grained soils that trap contaminants in the water and sorbed phases while the transmissive zone is the high permeability coarse-grained soils that allow advective transport of contaminants.
** In the saturated zone

Saturated soil samples collected from 18CPT01 in the 2013 investigation adjacent to MW-2 did not imply the presence of DNAPL in this area of the site, although the concentrations of TCE and MC in groundwater were high (TCE in MW-2 at 6.2% of solubility and MC in MW-2 at 6.8% of solubility in May 2013). This observation implies that use of 1% of solubility as an indicator for the presence of DNAPL is conservative and a concentration of 5% to 10% provides a better approximation of DNAPL presence at this site.

An estimate of the amount of DNAPL present can be estimated using **Figures 2-1 and 2-2**, where an approximation of the extent of DNAPL in the vicinity of the UEP and ACD is made. Using the estimated saturated soil concentrations, thickness of soil where DNAPL might be present, and the aerial extent of DNAPL from **Figures 2-1 and 2-2**, an estimate of TCE and MC mass is made. **Table 2-7** presents a summary of the calculations and results. The mass of MC in DNAPL is estimated at 80,000 lbs and the mass of TCE is estimated at 132,000 lbs. Because residual DNAPL is not present in a continuous, connected form but rather it occurs in disconnected globules or stringers trapped inside pore space, the volume of DNAPL as determined above likely overestimates the potential DNAPL quantity. The actual lateral extent, distribution, and concentrations of DNAPL cannot be determined from discrete samples and

because of its discontinuous nature, it is not readily identified. This phenomenon also makes identifying and treating residual DNAPL difficult.

2.4.2.3 Lateral Extent and Migration of CoCs

The ongoing shallow groundwater extraction has been effective at reducing the extent of contamination. **Figure 2-3 and Figure 2-4** show the MC and TCE plumes in the shallow zone as of November 1992, prior to the IRA and operation of the groundwater extraction system and treatment plant. Comparing these figures to **Figure 1-13** and **Figure 1-11**, respectively illustrates that the extent of the shallow zone plumes have decreased over time. The current extent of MC contamination is greatly reduced with respect to historical results. The horizontal extent of MC contamination in groundwater is limited to two distinct areas located within the containment area: in the vicinity of monitoring wells 120 and AWD-1 and extraction trenches ICT-12D and ICT-12E, and in the vicinity of MW-2 extending to MW-1 to the west and MW-21 to the east, with the highest concentration reported at monitoring well MW-2. The vertical extent of MC is mostly shallow, although detections in 18CPTMW01SW at 746 µg/L and in MW-14 at 53.5 J µg/L were reported in June 2016 in the upper Wilcox Formation.

In earlier sampling events, TCE concentrations exceeding the MCL were found in almost every well at LHAAP-18/24. The current extent of TCE contamination is consistent with historical results. However, the magnitude of the isoconcentration contour lines has decreased by approximately one order of magnitude. The horizontal extent of TCE contamination in groundwater covers the entire containment area, and extends outside the containment area southwest to MW-8 and MW-19, northwest to 18CPTMW-23, northeast to 18WW17 and C-08, and to the southeast to 18CPTMW14.

No equivalent comparison of plume extent changes is possible for perchlorate because perchlorate was not tested prior to implementation of the IRA. **Figure 2-5** shows the perchlorate shallow zone plume as of April 2001, more than three years after initiation of the IRA. Due to mobility of perchlorate, the shallow zone plume extent has undergone only limited reduction in the past 13 years when compared to **Figure 1-9** from June 2016. Historically, perchlorate concentrations exceeding the GW-Ind of 72 µg/L were found at two shallow zone wells (MW-17 and MW-19) that now have concentrations less than the current cleanup criteria of 17 µg/L (TRRP PCL). Concentrations of perchlorate in the shallow zone have been reduced in certain wells, such as in MW-2 from 40,000 µg/L in April 2001 to 33.3 µg/L in June 2016, but increased in other wells such as MW-23 from 4,080 µg/L in April 2001 to 65,200 µg/L in June 2016 and in MW-21 from 4,510 µg/L in April 2001 to 26,100 µg/L in June 2016. Additionally, investigation work completed between March and May 2013 resulted in identification of an area in the vicinity of 18CPTMW22 with a very high perchlorate concentration (106,000 µg/L in June 2014). A new upper Wilcox monitoring well (18CPTMW22SW) was installed in September 2014 and sampled in December 2014. The perchlorate concentration in this well was reported at 17,300 µg/L, which is lower than the concentration reported in plugged monitor well 18CPTMW22, but indicates that perchlorate is present in the upper Wilcox aquifer. In May 2014, an attempt to install a Shallow Zone well near C-01 to the south of 18CPTMW22 for lateral delineation of perchlorate in the Shallow Zone groundwater was made but the Wilcox clay was very shallow (only 13 feet bgs) and the upper soil was damp (no water was identified). Therefore, a well was not installed. Instead three (3) soil samples were collected at 6, 12, and 16 feet bgs and analyzed for perchlorate. No perchlorate was present at detection limits of 2.08 to 2.40 µg/kg, providing a

southern boundary to the extent of perchlorate in this area of the site. The 6 and 12 foot samples were collected from the transmissive Shallow Zone and the 16 foot sample was collected from the Wilcox clay.

To determine the lateral and vertical extent of perchlorate and the presence of a perchlorate source in this area of the site, 17 borings were installed in the Shallow Zone and soil samples were collected in the Spring of 2016. The results indicate the absence of a perchlorate source, defined the extent of perchlorate in the vicinity of 18CPTMW22, and determined that perchlorate from LHAAP-18/24 does not appear to be migrating to LHAAP-17, although new Shallow Zone monitoring well 18CPTMW26 had insufficient water to collect groundwater samples. New monitoring well 18CPTMW22R was intended to be completed in the Shallow Zone, however, it was completed in the first groundwater encountered, which is actually perched groundwater above the Shallow Zone. The perchlorate concentration is a sample from 18CPTMW22R was 0.917 µg/L in June 2016, which is much lower than the concentration detected in a sample collected from 18CPTMW22 in June 2014 of 106,000 µg/L. Monitoring well 18CPTMW22 was screened in the Wilcox clay and into the upper Wilcox sand. Soil data from this area of the site indicate that perchlorate resides primarily in the Wilcox clay compared to the unconsolidated soil of the Shallow Zone.

Monitoring wells 18CPTMW22DW, 18CPTMW26, and 18CPTMW26SW were installed in this area of the site in April 2016. The groundwater data from 18CPTMW22DW determined the vertical extent of perchlorate in the Wilcox Formation. Monitoring well 18CPTMW26 had insufficient water to collect groundwater samples and 18CPTMW26SW had a perchlorate concentration of 6.42 µg/L below the PCL of 17 µg/L, providing later extent of perchlorate between LHAAP-18/24 and LHAAP-17 in the Wilcox Formation. No VOCs or 1,4-dioxane were detected in this area of the site.

Perchlorate approaching Harrison Bayou at 18WW08 in the shallow zone has decreased from a high of 36,300 µg/L in 2002 (map not shown) to 3.36 µg/L in June 2014 and < 0.20 µg/L in June 2016, with an overall decreasing trend (table below). No perchlorate was detected north of Harrison Bayou in 18CPTMW16 (< 0.20 µg/L), sampled in June 2016. Due to disruption of electric power and operational disruptions associated with the sand filter, the extraction system was temporarily shut down in summer 2009. This disruption of power during the summer of 2009 caused migration of perchlorate towards 18WW08 with perchlorate concentration increasing from 220 µg/L in April 2009 before power disruption to 450 µg/L in September 2009 and 2,700 µg/L in September 2010. The increase in perchlorate in 18WW08 continued to be observed one year after power was restored due to the travel time of groundwater between the ICT-13 series and 18WW08.

Monitoring Well 18WW08	
Year	**Perchlorate (µg/L)**
2000	18,000
2002	36,300 (maximum)
November 2005	13,200
April 2009	220
September 2009	450

Monitoring Well 18WW08	
Year	**Perchlorate (µg/L)**
September 2010	2,700
May 2013	51.2
June 2014	3.36
June 2016	< 0.20 (minimum)

The temporary shutdown of the GWTP in summer 2009 may have allowed perchlorate to travel toward Harrison Bayou as observed in MW-16 (concentration increased from < 0.3 µg/L on September 30, 2009 to 5,500 µg/L on March 10, 2010). This could occur because of the presence of a gap in the ICT liners between ICT-12E and ICT-13A and also due to the absence of a clay layer that otherwise would separate the shallow zone from the Wilcox formation. Perchlorate fell to 800 µg/L on July 6, 2010 and 17 µg/L in September 2010. The May 2013 concentration of perchlorate in MW-16 was reported at 166 µg/L. However, recent disruption in performance of ICT-12E and ICT-13B between June and September 2014 resulted in migration and increase in perchlorate concentration in MW-11 with a June 2014 reported concentration of 11,600 µg/L. Operation of ICT-12E and ICT-13B was resumed in October 2014. MW-16 was sampled in December 2014 and a perchlorate concentration of 3,580 µg/L (J-flagged) was reported, appearing to be reversing the increasing trend. The perchlorate concentration in MW-16 declined further and was reported at 0.615 µg/L in June 2016. The June 2016 horizontal extent of perchlorate in shallow zone groundwater (**Figure 1-9**) covers the entire containment area with extensions beyond the containment area southwest to MW-8, northwest to 18CPTMW15 and MW-16, northeast to 18WW17, and to the southeast to 18CPTMW14 and to 126.

Historical data for 1,4-dioxane were not useful due to high reporting limits. However, recent groundwater samples were collected for 1,4-dioxane. The June 2016 Shallow Zone groundwater results are presented in **Figure 1-15**. The highest 1,4-dioxane concentration was observed in monitoring wells 120 and MW-16, with lower concentrations in MW-7 and AWD-1.

Isoconcentration maps for the Wilcox Formation were presented in **Section 1.4**. **Figure 1-14** shows MC concentrations less than the MCL or undetectable in the majority of Wilcox Formation wells, with detections above the MCL in June 2016 at 18CPTMW01SW (746 µg/L) and MW-14B (53.5 J µg/L). **Figure 1-12** shows TCE concentrations exceeding the MCL at Wilcox Formation wells inside the containment area, with the maximum concentration reported in June 2016 for MW-14 at 15,900 µg/L and 12,700 µg/L from the bottom and top of the screened interval, respectively. Other wells exceeding the MCL for TCE in the Wilcox Formation are 18CPTMW01SW (46.5 µg/L), 18CPTMW08SW (74.2 µg/L), and 18CPTMW06SW (1.02 µg/L). **Figure 1-10** shows perchlorate concentrations exceeding the PCL in the Wilcox Formation only in 18CPTMW03SW (260 µg/L), 18CPTMW06SW (30.3 µg/L), 18CPTMW08SW (35,000 µg/L), 18CPTMW08DW (672 µg/L), 18CPTMW22SW (10,200 µg/L), and MW-14 (229,000 and 177,000 µg/L in the bottom and top portions of the screened interval).

The general lateral direction of groundwater flow in the shallow formation is from within the northern portion of the site to the east, north, and west. The mounding effect at the site in the shallow formation is present historically as depicted on the 1992 potentiometric map completed

by USACE (**Figure 1-8**). The extraction system has decreased the lateral extent of the mound, which extended to the south of the site towards MW-20 in 1992, but now is isolated to the northwestern portion of the site. The historical potentiometric gradient at the site indicates the gradient in the southern corner flows east, west and south. The presence of western and southern flow components of the historical gradient facilitated CoC migration outside the site boundaries in this area of the site. The current depiction of the potentiometric lines in the Shallow Zone in the southern area of the site (**Figure 1-6**) consistently shows that there is little horizontal gradient to the south to facilitate migration of CoCs outside the containment area. New Shallow Zone monitoring well 18CPTMW22R indicates the presence of a groundwater high in this area of the site. However, the groundwater elevations in 18CPTMW22R and MW-20 reflect the groundwater surface of a small perched unit, not the Shallow Zone groundwater. Therefore, there is no Shallow Zone groundwater surface high in this area. Figure 1-6, which is based on Shallow Zone groundwater elevations measured in June 2016, and excludes the elevations from 18CPTMW22 and MW-20, shows the most recently interpreted configuration of the Shallow Zone potentiometric surface. This configuration suggests that CoCs in the Shallow Zone groundwater may have migrated to the southwest part of the site before installation and operation of the extraction system.

Groundwater extraction generally decreased the groundwater elevation and the lateral extent of the high water mound, but did not significantly change the pattern of flow with the exception of the southern area of the site as discussed above. The highest groundwater elevation continues to occur in the vicinity of monitoring wells 123 and AWD-2. The potentiometric maps in the shallow saturated zone reflect influence from groundwater extraction, as depicted by the groundwater level depression represented by the 167 foot potentiometric line in the northeast site boundary. The influence of extraction is less pronounced in the northwestern boundary due to the presence of the groundwater high and ICT liners, and to the southwestern boundary due to the presence of ICT liners.

The presence of ICT liners in the northwest and southwest boundaries is associated with impeding CoCs from migrating from within the containment area to outside the containment area. These ICTs are generally terminated in the clay layer and, if intact, should provide barriers to flow away from the site. The exception was identified in the northwest corner of the site where the liners are not connected horizontally and the absence of the clay layer does not allow the liners to prevent CoCs from migrating beneath the liners under observed gradient conditions.

Historical data indicated that CoCs present outside the containment area have migrated beyond this area prior to the installation of the ICTs and liners; particularly the area to the southwest. While the presence of liners prevents migration of contaminants from within the containment area to outside the containment area, the liners also prevent extraction of contaminants on the downgradient side of the ICT.

2.4.2.4 CoC Mass Distribution in the Shallow Zone

An estimate of CoC mass within the containment area versus outside the containment area was determined. The calculations included analysis of dissolved and adsorbed mass of CoCs following assumptions and calculations presented in **Table 2-5** and **Table 2-6,** the only difference being that areas covered by the isocontour lines for each CoC were divided between areas inside the containment and areas outside the containment. **Table 2-8** presents the mass

calculations for the areas outside the containment area for the dissolved and adsorbed phases. Using the calculated total CoC mass and CoC mass outside the containment area, the estimated mass within the containment area was determined and the fraction of CoC mass outside the containment area was determined. (See **Table 2-9**.)

The results in **Table 2-9** indicate that the majority of the CoC mass is inside the containment area (with the exception of perchlorate, located primarily to the west and northeast of the containment area). Additionally, the distribution of MC, TCE and perchlorate mass within the containment is primarily concentrated in the vicinity of the UEP and ACD areas. Distribution of perchlorate and TCE mass outside the containment area is concentrated to the west and southwest of the containment area. The northwestern area of the site is primarily composed of sandy soil in the Shallow Zone, without a clay layer. These coarse-grained areas are considered transmissive zones. The ICTs extract CoCs primarily from within the containment area based on their location within and at the perimeter of the containment area. 1,4-Dioxane is primarily located to the north of the ACD area.

2.4.2.5 Vertical Gradient and Connectivity

Groundwater gauging was conducted in June 2016 after completion of installation of 11 new Wilcox Formation monitoring wells. The gauging event allowed determination of depth to groundwater across the site in the shallow zone and Wilcox Formation wells and the vertical gradient occurring at the site. The June 2016 water level data (**Table 2-10**) generally indicate an upward gradient between the upper Wilcox and the shallow zone within the containment area, with the exception of areas in the vicinity of MW-5 and 18CPTMW04 adjacent to the former UEP. Other areas with a downward gradient include the vicinity of MW-9, 18WW11, 18CPTMW19, and 18CPTMW22R. All of these locations are outside the containment area. The vertical gradient between 18CPTMW22R and 18CPTMW22SW is reported at 8.22 ft. The upward gradients range between 0.07 ft and 3.67 ft while the downward gradients range between 0.05 ft and 8.22 ft.

A downward gradient is indicated between the shallow zone and the upper Wilcox Formation in the area of MW-5. The downward vertical gradient observed between the shallow zone and upper Wilcox Formation is likely associated with the lack of groundwater extraction in this area. (MW-5 is nearest to ICT-13F and ICT-13G. ICT-13F does not extract significant amounts of groundwater due to the low level of groundwater in that area of the site and ICT-13G continues to be non-operational, based on a decision that was made several years ago as a result of poor extraction quantities of groundwater from that area of the site.)

The 18CPTMW04 area, also with an observed downward gradient between shallow zone and upper Wilcox Formation, is adjacent to ICT-6, which was used as a re-injection trench between 2007 and 2012. Historical data from MW-1 located just to the south of ICT-6 indicated that the influence of re-injection was a significant increase in shallow zone groundwater elevation. While water re-injection ceased in June 2012, the vertical gradient continues to be in a downward direction with approximately 2 ft of head. This is likely due to lack of significant influence of other extraction trenches on the Shallow Zone groundwater in this area.

Upward gradients observed in the other areas of the site reflect the effect of ICT extraction reversing the natural downward gradient between the shallow zone and the upper Wilcox Formation. The areas near MW-2 and MW-22 are influenced by extraction in ICT-8, which has

one of the highest extraction quantities and a large area of influence. The MW-21 area is influenced by extraction in ICT-14D and ICT-14E, and monitoring wells 120/MW-14 area is influenced by extraction in ICT-12E and ICT-13A.

Outside the containment area, the well pairs indicate a mixture of downward and upward vertical gradients between the shallow zone and the upper Wilcox Formation.

Downward vertical gradients between the Shallow Zone and the Wilcox Formation drive CoCs downward. This is observed in several areas including areas where the current vertical gradient appears to be upward such as in the monitoring well pair 120/MW-14. The vertical gradient depicted in June 2016 was 1.78 ft in the upward direction. This implies CoC migration upward from MW-14 to monitoring well 120. However, this upward gradient is caused by the extraction system and historically the natural gradient is slightly downward that allowed the CoCs to migrate downward. Currently, the concentrations of CoCs in well pair 120/MW-14 is such that MW-14 contains higher concentrations of CoCs (e.g., perchlorate concentration in June 2016 in MW-14 is 229,000 μg/L from the bottom of the screen compared to 32,700 μg/L in monitoring well 120. A similar observation where the concentration of perchlorate in the Wilcox Formation is higher than in the Shallow Zone is in well pair MW-5/18CPTMW08SW where perchlorate concentrations are 31,300 μg/L and 35,000 μg/L, respectively. The June 2016 vertical gradient is 0.32 ft downward. In this area of the site the downward gradient has been observed fairly consistently. Generally, in all other areas of the site, regardless of the gradient direction (up or down) between the Shallow Zone and the Wilcox Formation, the Shallow Zone CoC concentrations are higher than the concentrations in the Wilcox Formation.

2.4.2.6 Mass Removal Flux

The CoC mass extracted by the GWTP was determined based on extraction rates measured on a monthly basis and concentrations in extraction locations measured annually. The mass flux for the first quarter of 2015 is presented in **Table 2-11,** and in **Table 2-12** for the first quarter of 2016. On average on a daily basis for the two year period, approximately 2.16 lbs of perchlorate, 1.85 lbs of TCE, and 1.98 lbs of MC were extracted from groundwater. Assuming future extraction rates and concentrations are similar to those observed in 2015 and 2016 (understanding that mass extraction rates naturally decrease as CoC mass decreases over time), the annual estimated mass removal rates are 0.39 tons per year (tpy) for perchlorate, 0.34 tpy for TCE, and 0.36 tpy for MC (**Table 2-13**).

Using the above extraction rates, CoC mass in groundwater, and the estimated total mass in the formation as discussed above, the estimated lifecycle for groundwater extraction at the site would be estimated as shown in **Table 2-14**. The estimated duration to remove the dissolved phase constituents is 2.0 years for MC, 2.4 years for TCE, and 18.5 years for perchlorate. To remove the adsorbed phase, assuming dissolution is not rate limiting, the estimated lifecycle duration for MC is 2.2 years and 4.4 years for TCE. In practice, the desorption of adsorbed mass is rate limiting and could increase the estimate lifecycle duration by multiples, if not orders of magnitude, especially as a large mass of VOCs is present in the lower permeability zones. The dissolution rate is a function of soil type, organic carbon content, contaminant characteristics, and concentration gradient between adsorbed and dissolved concentrations and will vary across the site based on localized variations in these factors.

Perchlorate mass was assumed to reside in the pore space, and not as brine. This is based on the fact that the highest concentration in groundwater reported at 229,000 µg/L in the bottom portion of monitoring well MW-14 measured in June 2016 is not high enough to imply the presence of perchlorate brine in the formation. For DNAPL, the estimated duration assuming dissolution of DNAPL at a non-limiting rate is 110 years for MC and 196 years for TCE. Therefore, groundwater extraction alone would not remediate groundwater quickly. The above estimates assume that groundwater extraction captures the entire extent of the CoC plumes, which is also not accurate. However, because groundwater extraction is successful in removing substantial amounts of contaminants, its importance as a remedy component remains, particularly in the short term.

First quarter 2013, 1st quarter 2015, and 1st quarter 2016 quarterly extraction rates of the three main CoCs, perchlorate, TCE, and MC, from each ICT and extraction well are presented in **Figures 2-6a, 2-6b,** and **2-6c,** respectively**.** Generally, the extraction rates increased for MC and TCE in 2015 and 2016 compared to 2013 but decreased for perchlorate. **Figures 2-7a, b, and c,** reflect 2013, 2015, and 2016 CoC extraction rates for boundary extraction ICTs, series 12, 13, and 14. The figures indicate that perchlorate has the highest removal rate in ICT-12 and ICT-13 series. Methylene chloride in ICT-14 series in 2016 reflects a high extraction rate. This was associated primarily with high MC concentrations in ICT-14C and ICT-14D. The figures also indicate that ICT-12 series along the southwestern boundary removes the highest mass of CoCs, followed by ICT-14 series along the northeastern boundary, then ICT-13 series along the northwestern boundary of the site. These varied removal rates reflect the varied contaminant concentrations and groundwater extraction rates (which reflect the natural ability of groundwater and CoCs to migrate in a certain area) with higher concentrations and groundwater extraction rates occurring for ICT-12 series and least for ICT-13 series. These varied conditions are important considerations for remediation design.

2.4.2.7 Assessment of GWTP Operations

Shallow groundwater extraction for treatment is currently occurring at LHAAP-18/24. As indicated above, it is estimated that 0.39 tpy of perchlorate, 0.34 tpy of TCE, and 0.36 tpy of MC, among other CoCs, are extracted from the shallow groundwater. This process not only reduces the quantity of CoCs in groundwater, but also influences potential lateral and vertical migration of CoCs in the containment area. The lateral gradient reversal observed primarily to the northeast, but also the northwest and southwest, is a result of groundwater extraction. The vertical gradient reversal between the Shallow Zone and the Wilcox Formation is also a result of groundwater extraction. These benefits cannot be substituted immediately by other remedial actions such as excavation, enhanced in situ biodegradation, or monitored natural attenuation (MNA). The importance and value of the GWTP will diminish when the CoC mass extracted by the GWTP becomes less than that occurring by other remedial actions, when containment by groundwater extraction becomes unnecessary because CoC concentrations and distribution is such that the groundwater plume is not expanding, and when the threat of vertical migration of CoCs diminishes due to reduced CoC concentrations in the Shallow Zone.

Contaminant removal rates are hindered by partitioning of the CoCs on the soil, particularly TCE and MC. Retardation for these compounds can be determined based on their partition coefficients, the soil bulk density, and the soil porosity. Using a soil bulk density of 1.95 kg/L,

total porosity of 0.396, and soil water partition coefficient for TCE and MC of 0.196 L/kg and 0.0213 L/kg, respectively, a retardation coefficient for TCE of 1.84 and for MC of 1.11 can be calculated. In practice, the content of the water that is actually moving is represented by the effective porosity, which is much lower than the total porosity but it is higher in coarse-grained soil and lower in fine-grained soils. Assuming an effective porosity of $1/10^{th}$ of the total porosity in fine-grained soil and ½ in coarse-grained soil indicates that the retardation coefficients in fine-grained soil could be as much as 10.0 for TCE and 2.04 for MC, and in coarse-grained soil as much as 2.67 for TCE and 1.21 for MC.

2.4.2.8 Natural Attenuation

Assessment of NA is important if MNA is utilized as part of the remedial alternative. **Appendix A** presents analysis of NA at the site and its role in remedial actions. The following were concluded from the NA analysis:

- It is believed that extraction of groundwater removes a greater mass of contaminants compared to NA mechanisms.
- Generally, it is not possible to differentiate between NA effects and effects of groundwater extraction on contaminant concentration decrease.
- The presence of TCE daughter compounds (1,2-DCE and VC) provides a good evidence of occurrence of NA at the site. TCE daughter compounds were identified in several wells (MW-2, MW-1, MW-4, MW-5, MW-7, MW-8, MW-14, MW-21, 109, 120, and AWD-1),
- Wells outside the influence of groundwater extraction such as 18WW08 and MW-8 provided evidence of occurrence of NA for perchlorate in 18WW08 and TCE in MW-8.

2.4.3 Wilcox Formation Groundwater

Human health risk assessment was not conducted on Wilcox Formation groundwater because very few Wilcox Formation wells were historically present within the contaminant zone. The majority of Wilcox Formation wells were located outside the containment area (e.g., C-01, C-10, C-04, 18WW02, 18WW03, 18WW09, and 18WW11) and most of these wells were either unimpacted or have very low concentrations of CoCs. Investigations completed in 2013/2015/2016 resulted in the installation of Wilcox Formation monitoring wells inside and at the boundary of the containment area. Several of these wells contain CoCs above their respective MCLs/PCLs. The analytical results from the June 2016 sampling event (**Table 2-15**) could be used as proxy for determining the CoCs in the Wilcox Formation. The criteria include:

- CoCs that are present in the Shallow Zone groundwater, and
- Chemicals that exceed their respective MCLs/PCLs.

The chemicals that are selected as COCs in the Wilcox Formation using the above rationale are included in **Table 2-16** for the carcinogenic chemicals and **Table 2-17** for noncarcinogenic chemicals. For the most part, the majority of the chemicals identified as CoCs in the Shallow Zone are selected in the Wilcox Formation.

The CoCs retained in **Table 2-16** for the LHAAP-18/24 groundwater are MC, TCE, PCE, benzene, VC, and 1,4-dioxane due to their contribution to risk or exceedance of their respective

MCL/PCL. Bromodichloromethane was retained on a provisional basis, although none of the wells had historically detectable concentrations of bromodichloromethane. Should future groundwater compliance sampling events reveal that bromodichloromethane is not present in groundwater at LHAAP-18/24 or below the PCL, this CoC will be eliminated from further evaluation. Chloroform was eliminated because the maximum concentration was below the PCL. 1,1,2-Trichloroethane was not retained because the maximum concentration is below the MCL. The other two chemicals, 2,3,7,8-TCDD and 4,4'-DDD, were not retained as CoCs for the reasons noted in the **Table 2-16**.

Based on calculations completed in the Shallow Zone groundwater concentrations, groundwater contaminants with HQ's greater than 0.1 are listed in **Table 2-17**. Some CoCs have MCLs. For those chemicals without MCLs, the TRRP PCLs were used for evaluation. The CoCs retained in **Table 2-17** for the LHAAP-18/24 groundwater are MC, TCE, perchlorate, cis-1,2-DCE, 1,3,5-trinitrobenzene, arsenic, barium, and 1,4-dioxane due to the contribution of the Wilcox Formation Revised Hazard Quotient to HI and/or exceedance of their respective MCL or PCL. Eight chemicals (chloroform, antimony, chromium, cobalt, manganese, nickel, silver, and thallium) were not retained as CoCs for the reasons noted in the **Table 2-17**.

Thus, the current CoCs for groundwater at LHAAP-18/24 are VOCs (MC, TCE, cis-1,2-DCE, benzene, VC, and 1,4-dioxane), metals (arsenic and barium), and the anion perchlorate. Tetrachloroethene and bromodichloromethane were retained on a provisional basis. Perchlorate, TCE, and MC present the vast majority of the human health risk in the Wilcox Formation. **Figure 1-10** presents the most recent (June 2016) perchlorate concentrations in the Wilcox Formation. The area of groundwater contaminated with perchlorate in the Wilcox Formation exceeding the PCL is estimated at 21 acres. **Figures 1-12, 1-14, and 1-16** present the TCE, MC, and 1,4-dioxane concentrations in Wilcox Formation groundwater using June 2016 data and **Figure 1-18** presents the metals exceedances. Cis-1,2-DCE is not presented separately because the plume for cis-1,2-DCE is enveloped by the TCE plume. The other CoCs are present in isolated locations, so plume maps for those CoCs have not been generated. The areas of groundwater in the Wilcox Formation contaminated with MC, TCE, and 1,4-dioxane are estimated at 4.8, 16.6, and 1.2 acres, respectively. The occurrences of other VOCs and metals detections in groundwater are intermittent and their distribution is generally not contiguous. In general, they do not present a clear pattern across the site.

The mass of dissolved-phase constituents in the Wilcox Formation was estimated for perchlorate, TCE, MC, and 1,4-dioxane. The basis of this analysis was the groundwater concentrations detected in June 2016 and the isocontour lines depicted in **Figures 1-10, 1-12, 1-14**, and **1-16** for perchlorate, TCE, MC, and 1,4-dioxane, respectively. The areas between each set of adjacent isocontour lines were determined. Each of these areas was represented by the average isocontour line concentrations. For the inner-most isocontour line, the average of the concentration represented by the isocontour line and the concentration represented by the monitoring well(s) was calculated to represent the concentration for that area of the isocontour line. The average thickness of groundwater in the Wilcox Formation was estimated based on the difference between depth of the bottom of the Wilcox clay layer and approximately 70 ft bgs, which is the approximate depth of the upper Wilcox Formation used in this analysis. In general, a thickness of 20 feet was used in this analysis.

The results of mass estimates are presented in **Table 2-18**. The estimated dissolved phase mass for perchlorate was 2,221 lbs, 212 lbs for TCE, 7.6 lbs for MC, and 2.6 lbs for 1,4-dioxane. The impacted thickness in the Wilcox Formation was assumed to be 20 feet representing the upper Wilcox portion of the aquifer (ranging from below the bottom of the Wilcox clay to 20 feet below the Wilcox clay). For example, in the central portion of the site represented by monitoring wells 18CPTMW01SW, 18CPTMW06SW, and 18CPTMW03SW and in the northwestern portion represented by 18CPTMW08SW, the upper Wilcox Formation ranges between approximately 45 feet bgs to 65 ft bgs; along the southwestern boundary represented by wells 18CPTMW10SW and 18CPTMW12SW, the upper Wilcox ranges between approximately 40 ft bgs and 60 ft bgs; in the southern area of the site represented by monitoring well 18CPTMW22SW, the upper Wilcox ranges between 30 ft bgs and 50 ft bgs; and in the northwestern area of the site represented by MW-14, the upper Wilcox ranges between 30 ft bgs and 50 ft bgs. For every one (1) foot increase in impacted thickness, the dissolved mass would increase by a factor of approximately 5%, assuming the groundwater concentrations remain unchanged. Therefore, the dissolved phase mass could differ from the values shown in **Table 2-18**. However, for the purposes of this analysis, a groundwater impacted thickness of 20 ft is used.

2.4.3.1 Estimate of CoC Mass in the Wilcox Formation

The mass of dissolved phase constituents in the Wilcox Formation was used to estimate the mass adsorbed on the soil matrix for TCE and MC. The equation and parameters used to determine soil saturation concentrations are discussed in **Appendix F** of the Updated PSI Report for LHAAP-18/24 (AECOM, 2016a). The equation is taken from the Texas Risk Reduction Program (TRRP) guidance (TRRP Tier 2 PCL Equations, March 2000). The parameters are taken from site specific conditions (organic carbon, porosity, and bulk density) and from literature published values for solubilities and partition coefficients (TRRP). **Table 2-19** presents these results for MC and TCE mass calculations in the soil. The estimated mass associated with the saturated soil for MC is estimated at 8.4 lbs and 389 lbs for TCE. A similar analysis was not done for perchlorate or 1,4-dioxane because perchlorate is a salt with complete solubility in water and 1,4-dioxane is miscible in water. The uncertainty associated with the dissolved mass estimation applies to estimation of CoC mass on the saturated soil.

2.4.3.2 DNAPL Analysis in the Wilcox Formation

At the concentrations identified in the Wilcox Formation, no DNAPL is suspected.

2.4.3.3 Lateral Extent and Migration of CoCs in the Wilcox Formation

Little historical information is available about the presence and distribution of CoCs in the Wilcox Formation. Therefore comparison to historical data is not possible. **Figures 1-10, 1-12**, **1-14, 1-16, and 1-18** provide the concentrations and distribution of perchlorate, TCE, MC, 1,4-dioxane, and metals in the Wilcox Formation based on June 2016 sampling results. In general, the concentrations and extent of CoCs in the Wilcox Formation is much smaller than identified in the Shallow Zone. Impedance of contaminant migration between the Shallow Zone and the Wilcox Formation occurs as a result of the presence of the Wilcox clay in a large area of the site. In areas where the Wilcox clay is absent, concentrations in the Wilcox Formation appear to be high such as in MW-14. However, this observation is not conclusive since high CoCs are identified at 18CPTMW08SW and 18CPTMW22SW, where the Wilcox clay is present.

The current perchlorate impact in the Wilcox Formation is concentrated in MW-14 to the west of the site, 18CPTMW08SW in the northern area of the site, and 18CPTMW22SW in the southern area outside the containment. Highest TCE and MC concentrations also reside in the vicinity of MW-14 and 18CPTMW08SW while 1,4-dioxane reside in the vicinity of MW-14. For metals, only arsenic and manganese had detections above the MCL/PCL in the Wilcox Formation in June 2016, noting that manganese concentration in the Wilcox Formation is lower than the background 95% upper confidence limit (UCL) determined in the Shallow Zone from perimeter wells.

The general lateral direction of groundwater flow in the Wilcox Formation is from within the northwestern portion of the site radially outward to the east, north, west, and south.

2.4.3.4 CoC Mass Distribution in the Wilcox Formation

An estimate of CoC mass within the containment area versus outside the containment area in the Wilcox Formation was determined. The calculations included analysis of dissolved and adsorbed mass of CoCs following assumptions and calculations presented in **Table 2-18** and **Table 2-19,** the only difference being that areas covered by the isocontour lines for each CoC were divided between areas inside the containment and areas outside the containment. **Table 2-20** presents the mass calculations for the areas outside the containment area for the dissolved and adsorbed phases. Using the calculated total CoC mass and CoC mass outside the containment area, the estimated mass within the containment area was determined by the difference and the fraction of CoC mass outside the containment area relative to the total mass was calculated. (See **Table 2-21**.)

The results in **Table 2-21** indicate that the majority of the CoC mass is inside the containment area (with the exception of perchlorate, located primarily to the southwest of the containment area). Additionally, the distribution of MC, TCE and perchlorate mass within the containment is primarily concentrated in the vicinity of the UEP and ACD areas, and in the ACD area for 1,4-dioxane.

2.4.3.5 Vertical Gradient and Connectivity within the Wilcox Formation

Groundwater gauging was conducted in June 2016 after completion of installation of 11 new Wilcox Formation wells. The gauging event allowed determination of depth to groundwater across the site in the upper and lower Wilcox Formation wells and the vertical gradient occurring at the site. The June 2016 water level data in the Wilcox Formation (**Table 2-10**) generally indicate mixed gradients, with a downward gradient within the containment area and an upward gradient outside the containment area.

The two well pairs inside the containment (18CPTMW01SW/18CPTMW01DW and 18CPTMW08SW/18CPTMW08DW) have a downward gradient. In general for the Wilcox Formation, the concentrations in the lower Wilcox are lower than the concentrations in the upper Wilcox. Good examples of the decrease in concentration with depth are for well pair 18CPTMW08SW/18CPTMW08DW and 18CPTMW22SW and 18CPTMW22DW for perchlorate. Perchlorate concentrations for well pair 18CPTMW08SW/18CPTMW08DW in June 2016 are 35,000 μg/L and 672 μg/L and the June 2016 perchlorate concentrations for well pair 18CPTMW22SW/18CPTMW22DW are 10,200 μg/L and 1.21 J μg/L, respectively. The only location where CoCs increase with depth is in MW-14. In June 2016, samples were collected

from near the top of the screen and the bottom of the screen. The results indicated that concentrations of perchlorate, TCE, MC, and 1,4-dioxane were higher at the bottom of the screen compared to the concentrations at the top of the screen (e.g., perchlorate concentration was 177,000 μg/L at the top of the screen compared to 229,000 μg/L at the bottom and 1,4-dioxane concentration was 390 μg/L at the top of the screen compared to 412 μg/L at the bottom of the screen).

2.4.4 Vertical Mass Flux Determination

As indicated in **Table 2-10**, groundwater elevations at several co-located wells inside and outside the containment area indicate a downward gradient between the Shallow Zone and the upper Wilcox Formation. These downward gradients were used to determine the potential vertical mass flux of CoCs across the Wilcox clay, where it is present. Where the Wilcox clay is absent, a Wilcox clay thickness of 0.1 ft was used for the calculations. The vertical gradient was determined by dividing the head difference by the clay thickness. **Table 2-22** provides the calculations of the mass flux for the main CoCs, perchlorate, TCE, and MC. Information about the clay characteristics such as porosity, hydraulic conductivity, bulk density, and organic carbon content was obtained from data collected in the 2013 investigation (AECOM, 2016a). An effective porosity of 11% is 25% of the reported total porosity of 44% for the clay. Organic carbon partitioning coefficients (koc) for MC and TCE were obtained from 30TAC 350.73(c) from which the distribution coefficients were determined. Retardation coefficients and transport velocities for MC and TCE were determined based on the compound-specific and Wilcox clay characteristics described above. The mass flux through the clay was determined based on CoC concentrations in the Shallow Zone groundwater and transport velocities for each CoC through the clay. **Table 2-22** provides the equations used in determining flux per unit area through the clay. Eventually to determine a total mass flux, the average flux was determined and a hypothetical area of 50 acres was assumed to represent the area of contamination in the Shallow Zone. The total flux through the clay was determined by multiplying the flux per unit area by the assumed area. It was also assumed that contamination has been present at the site for 70 years. Based on these assumptions, the mass of each CoC was determined (**Table 2-22**). The total mass for all three COCs was determined to be 2.01 lbs.

In comparison, the total mass in the Wilcox Formation determined for MC, TCE, and perchlorate is 2,840 lbs. (**Table 2-21**). The ratio between the estimated mass in the Wilcox Formation, based on measured concentrations and aerial extent, and the mass based on mass flux over 70 years is approximately 1,413. This discrepancy can be explained by the following factors:

- The Shallow Zone concentrations used in the mass flux determination are the June 2016 concentrations. Actual historical Shallow Zone concentrations were much higher before operating the Shallow Zone groundwater extraction system, which began operation in 1997/1998 and has removed a significant amount of contaminant mass from the Shallow Zone. Examples of the significant reduction in concentrations over time are presented for monitoring wells MW-2 and MW-7 as follows.

Ratio of Historical Maximum CoC Concentration to June 2016 Concentration in MW-2 and MW-7

CoC	MC	TCE	Perchlorate
MW-2 (inside containment)			
Maximum Historical Concentration (mg/L)	26,720 (June 1994)	1,520 (April 1994)	40 (April 2001)
June 2016 Concentration (mg/L)	21.3	15.5	0.033
Ratio	1,254	98.1	1,212
MW-7 (outside containment)			
Maximum Historical Concentration (mg/L)	1.7 (April 1994)	22.3 (November 2004)	157 (November 2003)
June 2016 Concentration (mg/L)	0.0025	1.74	22.2
Ratio	680	12.8	7.1

As can be seen from the data for monitoring wells MW-2 and MW-7, the ratio of perchlorate between the maximum reported concentrations and the most recent concentrations ranges between 7.1 and 1,212. The 1 to 3 orders of magnitude reduction in concentration of these CoCs explains the discrepancy between the total estimate of mass migrating to the Wilcox Formation calculated using the June 2016 results, compared to the total estimated mass in the Wilcox Formation for each CoC (**Table 2-21**). Similar ratios are obtained for other wells.

- The other important factor that provides additional explanation for the discrepancies identified above is related to the historical head differences between the Shallow Zone and the Wilcox Formation compared to current head differences between these water-bearing zones. Historically and prior to operating the extraction system, the groundwater head in the Shallow Zone was higher by up to 5 feet or more than observed today. The higher head differences historically present at the site provided a greater force driving the CoCs across the clay unit. For example a historical head difference between the Shallow Zone and the Wilcox Formation of five feet has a 10 times greater driving force than a head difference of ½ foot observed today.
- Another important factor that cannot be quantified is the historical installation of several BH-series wells into the Wilcox Formation around the UEP area. These wells were plugged due to the concern for contaminant migration from the Shallow Zone to the Wilcox Formation via these wells.
- Other less critical factors include the differences in hydraulic conductivity and organic carbon fraction values used in the calculations, compared to the actual values at the various locations.

Nonetheless, the determination above implies that movement of CoCs through the Wilcox clay takes place under groundwater head differences that create a downward hydraulic gradient between the Shallow Zone and the Wilcox Formation.

2.5 Conceptual Site Model

LHAAP-18/24 is a 34.5-acre site that has been impacted primarily with VOCs and perchlorate. 1,4-dioxane was also recently added to the site CoCs in groundwater. The area had been used for

the treatment, storage, and disposal (TSD) of solid and liquid explosive, pyrotechnic, and combustible solvent waste by open burning/open detonation, incineration, evaporation, and burial. Burning Ground No. 3 operated between 1955 and 1998. Historical waste management units include open burn pits, the UEP, stockpiles of solvent-soaked sawdust, and suspected waste burial pits. The UEP was constructed at the burning ground in 1963 as a holding pond to store explosive wastes resulting from the washout of rocket motor casings. In 1973, the pond also began receiving waste water containing solvent residues and solids. An ACD was built in 1979 for the purpose of disposing of explosive and explosive-contaminated wastes by burning. A groundwater extraction system incorporating approximately 5,000 feet (ft) of ICTs and a GWTP was installed in 1997 to control the migration of contaminated groundwater as an interim remedial action. Please refer to **Section 1.3** for additional details.

There are two groundwater zones at LHAAP-18/24: a "Shallow Zone" extending from the surface to a depth of approximately 45 ft bgs, and the Wilcox Formation below the Shallow Zone (please refer to **Sections 1.5 and 1.6** for additional details). Generally, these two units are separated by a contiguous clay layer which is believed to be present across the entire site with the exception of the area to the west and northwest towards Harrison Bayou (i.e., within the floodplain of Harrison Bayou). The Shallow Zone is heterogeneous composed of discrete layers of fine-grained and coarse-grained soils while the Wilcox Formation is characterized primarily with fine-grained sand.

The groundwater in the Shallow Zone flows radially outward from the northwestern area of the site. Localized influence of groundwater extraction can be observed in the shallow aquifer. The groundwater flow pattern and gradient direction in the Wilcox Formation is similar to what is observed in the shallow zone. Groundwater in the Wilcox Formation near LHAAP is currently used as a drinking water source (please see **Section 1.5** for additional details).

The major contaminants at the site are perchlorate and VOCs. 1,4-dioxane was recently added as a CoC in Shallow Zone groundwater. Residual contaminants remained in the unsaturated soil after completion of an interim remedial measure in 1997 whereby 32,000 cubic yard of source area soil were excavated and treated by low temperature thermal desorption.

The contaminants in the saturated zone occur in two forms: residual DNAPL in defined areas within the containment totaling an estimated aerial extent of 40,000 ft^2 (former UEP and former ACD areas) and dissolved plume within the containment area and outside the containment area where contaminants have migrated off-site before the installation of the interim remedial measure (groundwater extraction with 5,000 ft of ICTs and a GWTP which were installed in 1997 to control the migration of contaminated groundwater). Dissolved phase contaminants and DNAPL appear to have migrated from coarse-grained soils to fine-grained soils. Additionally, sorbed contaminants on the soil occur in areas where dissolved CoCs are present. The presence of contaminants in fine-grained soil and in the form of DNAPL provides for a long-term source at the site.

A 14-compartment model as developed by Sale and Newell and discussed in the ITRC document entitled: Integrated DNAPL Site Strategy, November 2011 was discussed. The model determined the presence of DNAPL in the lower conductivity (K) zones but not in the transmissive coarse-grained zones which is indicative of a mature plume that has undergone extraction via the existing groundwater extraction system. The aqueous and sorbed phases of VOCs are also high

in both the lower K and high K zones based on the high concentrations being extracted from the ICTs.

The model also determined that extraction of groundwater continues to remove an important mass of contaminants present in the transmissive zone and/or transported to the transmissive zone via diffusion from the lower K zones at the interphase between these zones and the presence of a source mass within the lower K zones will continue to serve as a persistent source of groundwater contaminants for a long time. The 14-compartment model also indicates that removal of the source of contaminants within the lower K zones in the source area is required to reduce the lifecycle of the site. The presence of the majority of DNAPL/residual mass in lower K zones, would hinder contaminant extraction or distribution of injected chemicals.

The Installation-Wide Baseline Ecological Risk Assessment (Final Installation-Wide BERA – Shaw, 2007b) did not identify potential risk to ecological receptors at LHAAP-18/24. Should there have been any ecological risk, it would have been expressed by this point in time. The BERA Addendum completed in 2014 (AGEISS, Inc., July 8, 2014) did not change the conclusion of the 2007 BERA.

Figure 2-8 illustrates the human health CSM for LHAAP-18/24. This model presents those exposure pathways that are hypothetically complete and being considered for remediation. Those exposure pathways that are likely to be incomplete or have negligible impact are not considered for remediation as discussed below.

VOCs and associated 1,4-dioxane, metals, and perchlorate releases associated with past operations of the former burn pits, burial trenches, the ACD, and the UEP are the suspected contamination sources at LHAAP-18/24. The majority of the unsaturated soil contaminated with these CoCs was remediated during an IRA. A risk assessment for soil was conducted with a hypothetical future maintenance worker's exposure to soil at LHAAP-18/24. The risk assessment determined the carcinogenic risk was determined to be 5.0×10^{-7}, which is less than the USEPA target risk range of 1×10^{-4} to 1×10^{-6} ELCR. The non-carcinogenic hazard was determined to be 0.042, which is less than the acceptable HI of 1. Therefore chemicals in soil at LHAAP-18/24 do not pose unacceptable carcinogenic risk or non-carcinogenic hazard to human health.

As discussed in **Section 1.8**, unsaturated soil known to contain CoCs constituting a potential source of CoCs to groundwater is isolated to locations south of the former UEP (as defined by locations 18SB02 for TCE at a depth of 10 to 12 ft bgs, location 8A-911 for MC at a depth of 8 ft bgs) and location 8A-975 (for MC at a depth of 5.5 to 12 ft bgs), to the west of the UEP (as defined by 18CPTBB02 at a depth of 4.5 to 5.5 ft bgs for perchlorate), and underneath the UEP (as defined by 18CPTUEP05 for MC at a depth of 24 to 25 ft bgs and 18CPT21/18CPT25 at a depth of 15 to 22 ft bgs). Therefore, the potential leaching of contaminants from the unsaturated soil at these locations to groundwater is considered a complete transport pathway that will be addressed during the remedial action. Other than the above-stated unsaturated soil locations, the medium of concern at LHAAP-18/24 is the groundwater.

Contamination, in the form of VOCs, 1,4-dioxane, metals, and perchlorate in the shallow groundwater at LHAAP-18/24, poses a potential risk to the hypothetical future maintenance worker. This is an exposure pathway at LHAAP-18/24 that was considered complete and has been determined to require remediation to manage this hypothetical risk. Concentrations of VOCs and perchlorate were detected in wells screened in the Shallow Zone and in localized

areas in the Wilcox Formation, though Shallow Zone contamination is much more widespread. The Shallow Zone and Wilcox Formation are hydraulically separated by a clay layer that extends over the majority of the site, with the exception of the area to the northwest towards Harrison Bayou. Potential interaction between the Shallow Zone and Wilcox formation in this northwestern area of the site warrants consideration during evaluation of remedial alternatives. The most significant contaminants in groundwater are MC, TCE, and perchlorate. It is implied that MC and TCE are present as residual DNAPL in the saturated zone at two locations in the former UEP and former ACD areas as discussed above. Another transport pathway that was considered potentially complete is the migration of Shallow Zone groundwater to surface water via seepage. This transport pathway is currently mitigated by the operation of a groundwater extraction system that prevents migration of contaminants to surface water as depicted in **Figure 2-8**. For the purposes of the CSM, this applies to Harrison Bayou and Caddo Lake because the point of compliance for Caddo Lake as it relates to discharge of groundwater to surface water is Harrison Bayou at LHAAP-18/24. The RI (Jacobs, 2001) concluded that LHAAP-18/24 does not appear to be significantly affecting the surface water based on surface water sampling data. Quarterly surface water sampling serves as verification of this determination. However, the main reason of apparent lack of migration of CoCs to surface water is, as indicated above, groundwater extraction associated with the interim remedial measure implemented in 1997 as part of the interim ROD. Additionally, the baseline risk assessment (Jacobs, 2002) did not link any surface water risks to LHAAP-18/24. However, concentrations of several CoCs in the shallow groundwater at LHAAP-18/24 exceed their MCLs/PCLs. Currently, discharge of these contaminants to Harrison Bayou is restricted by the on-going groundwater extraction. This observation was confirmed by data collected from 18CPTMW16, installed on the north side of Harrison Bayou.

Contamination, in the form of VOCs, 1,4-dioxane, metals, and perchlorate in the Wilcox Formation at LHAAP-18/24, also poses a potential risk to the hypothetical future maintenance worker. The magnitude of risk posed by Wilcox Formation groundwater is less than the risk posed by the Shallow Zone groundwater.

Residual DNAPL in the Shallow Zone groundwater was reported in two areas of the site (vicinity of former UEP and former ACD areas) primarily in the Wilcox clay, which is expected to constitute a source for a long period of time unless this mass is removed. Continued residual DNAPL dissolution of CoCs to groundwater is considered a complete transport pathway that will be evaluated in this FS.

A material balance for the four main contaminants (perchlorate, TCE, MC, and 1,4-dioxane) was completed in the Shallow Zone and Wilcox Formation and remediation duration estimates were determined for the Shallow Zone groundwater based on current groundwater extraction rates. These estimates did not take into account the diffusivity limitations associated with sorbed mass and DNAPL trapped in lower K zones. The estimates also assumed that the groundwater extraction system captures all impacted groundwater plumes. The estimated remediation durations ranged between 4 years for 1,4-dioxane and 200 years for TCE (**Table 2-14**). Understanding the limitations of contaminant release associated with the presence of DNAPL in lower K zones and sorbed mass within the lower K and high K zones, the durations associated with remediation by groundwater extraction are likely to exceed 1,000 years.

In summary, the CSM for the site described the complexity of the site with contaminants distributed among various heterogeneous zones. The CSM also determined that groundwater extraction minimizes or eliminates the expansion of the groundwater plume laterally and vertically, and continues to remove contaminant mass from groundwater. However, the CSM also determined that the lifecycle duration for the site under groundwater extraction is long, primarily because the majority of the contaminant mass is sorbed in lower K zones and/or present as residual DNAPL trapped in lower K zones.

Table 2-1: Chemicals Contributing to Carcinogenic Risk in Shallow Zone Groundwater

Chemical	ELCR [a]	EPC [a] (µg/L)	Well	Revised ELCR	Recent Maximum (µg/L)	Date	Well	MCL (µg/L)	TRRP PCL (µg/L)	Retained as a CoC?
Methylene chloride	4.0×10^{-1}	7,300,000	MW-2	b	21,300	06/24/16	MW-2	5	—	Yes, 1
Trichloroethene	4.1×10^{-2}	210,000	MW-2	b	17,100	06/16/16	120	5	—	Yes, 1
2,3,7,8-TCDD	1.1×10^{-5}	530	95 UCL[d]	None More Recent				3.0×10^{-5}	—	No, 2
4,4'-DDD	1.3×10^{-6}	59	MW-2	None More Recent				—	3.8	No, 2
Tetrachloroethene[3]	—	—	—	—	85.1	06/24/16	MW-2	5	—	Yes, 1
Benzene[3]	—	—	—	—	< 62.6	06/24/16	MW-2	5	—	Yes, 1
1,1,2-Trichloroethane[3]	—	—	—	—	< 50	06/07/16	AWD1B	5	—	Yes, 1
Vinyl Chloride[3]	—	—	—	—	256	06/07/16	AWD-1	2	—	Yes, 1
1,4-Dioxane[3]	—	61.7	95 UCL[d]	—	412	06/07/16	MW-14	—	9.1	Yes, 1
Chloroform [d]	4.2×10^{-5}	28	95 UCL[d]	b	58.1	06/24/16	MW-2	—	240	No, 2, 4
Chemicals Retained on a Provisional Basis										
Bromodichloromethane [c]	2.3×10^{-6}	530	18WW09	b	< 125	06/24/16	MW-2	—	15	Yes, 1

Notes and Abbreviations:

1. Identified as a COC since EPC and/or Recent Results are above the MCL or PCL.
2. Combined Shallow Zone ELCR of Chemicals with no MCL is within acceptable range of 1×10^{-6} to 1×10^{-4}.
3. Included as contributing chemicals due to their frequency of detection above the MCL or PCL in recent sampling events (see Table 2-3).
4. Excluded as a COC as maximum concentration in the Shallow Zone is below MCL/PCL.

a. From Baseline Risk Assessment Table C-53 (Jacobs, 2002).
b. Revised ELCR not calculated for chemicals with an MCL.
c. All other wells were < 15 ug/L (the majority were below detection). Bromodichloromethane will be re-evaluated when data with lower reporting limit are obtained for MW-2.
d. Using ProUCL for the results of samples collected in June 2016.

95 UCL indicates that the EPC was calculated rather than the maximum concentration at a specific well.
CoC contaminant of concern
ELCR excess lifetime cancer risk
EPC exposure point concentration

TRRP PCL Texas Risk Reduction Program Protective Concentration Level (Tier 1 Groundwater Residential)
MCL maximum contaminant level from the Safe Drinking Water Act
µg/L micrograms per liter

Table 2-2: Chemicals with Hazard Quotient Greater than 0.1 in Shallow Zone Groundwater

Chemical	HQ	EPC [a] (µg/L)	Well	Revised HQ	Recent Maximum (µg/L)	Date	Well	MCL (µg/L)	TRRP PCL (µg/L)	Retained as a CoC?
Methylene chloride	1600	7,300,000	MW-2	b	21,300	06/24/16	MW-2	5	—	Yes, 1
Trichloroethene	800	210,000	MW-2	b	17,100	06/16/16	120	5	—	Yes, 1
Perchlorate	750	69,000	18WW17	2,500	82,900	06/21/16	18WW17	—	17	Yes, 2
Chloroform	16	28	95 UCL[d]	b	58.1	06/24/16	MW-2	—	240	No, 5
cis-1,2-Dichloroethene	0.3	250	95 UCL[d]	b	43,600	06/24/16	MW-2	70	—	Yes, 1
1,4-Dioxane[6]	—	61.7	95 UCL[d]	—	220	06/16/16	120	—	9.1	Yes, 1
Antimony	8.1	333	95 UCL[d]	b	1.49	06/17/16	MW-16	6	—	No, 5
Barium	0.84	6,000	MW-1	b	10,300	06/13/16	18CPTMW24	2,000	—	Yes, 1
Chromium	0.12	18,000	MW-1	b	4,620	06/16/16	18WW16	100	—	Yes, 1
Manganese	1.7	8,270	MW-1	1.1	5,290	06/29/16	18WW25	—	1,100*	No, 7
Nickel	4.7	9,600	MW-1	7.0	14,300	06/16/16	18WW16	—	490	Yes, 3
Silver	0.94	480	MW-1	< 0.002	< 1	June 2016	All wells	—	120	No, 4
Thallium	0.47	3.7	MW-2	b	0.821	06/17/16	109	2	—	No, 5
Chemicals Retained on a Provisional Basis										
Arsenic[6]	—	—	—	—	16.1	06/21/16 06/13/16	18CPTMW18 18CPTMW24	10	—	Yes, 1
Cobalt	0.14	280	MW-1	0.178	355	06/16/16	18WW16	—	240	Yes, 1
1,3,5-Trinitrobenzene	0.33	1,000	MW-2	No Recent Data				—	730	Yes, 3

Notes and Abbreviations:

1. Identified as a COC since EPC and/or Recent Results are above the MCL or PCL.
2. Identified as COC since hazard quotient (HQ) is > 0.1 and EPC and recent results are above the TCEQ PCL.
3. Retained as a COC since revised HQ > 0.1 and sum of HQs may exceed 1.0.
4. Excluded since Revised HQ < 0. 1 using recent maximum concentration and chemical concentration is < PCL.
5. Excluded since Recent results are all less than the MCL or PCL, and pattern of detections does not indicate association with site contamination.
6. Included as contributing chemicals due to their frequency of detection above the MCL or PCL in recent sampling events (see Table 2-3).
7. Excluded because maximum concentrations of recent results are below the background 95%UTL.

a. From Baseline Risk Assessment Table C-50 (Jacobs, 2002).
b. Revised HQ not calculated for chemicals with an MCL or PCL.
c. Using ProUCL for the results of samples collected in June 2016

95 UCL indicates that the EPC was calculated rather than the maximum concentration at a specific well.

CoC	contaminant of concern
EPC	exposure point concentration
HQ	hazard quotient
MCL	maximum contaminant level from the Safe Drinking Water Act
ND	non detect
TRRP PCL	Texas Risk Reduction Program Protective Concentration Level (Tier 1 Groundwater Residential)
UCL	upper confidence limit
µg/L	micrograms per liter

* 95% UTL value from Final Evaluation of Perimeter Well Data for Use as Groundwater Background (Shaw, 2007) for Manganese is 7,820 µg/L, which is above the TRRP Tier 1 Groundwater Residential PCL thus the background value will be considered the Cleanup Level for Manganese.

Table 2-3: Constituents Added to the Chemicals of Potential Concern in the Shallow Zone

* Results when all five chemicals were not detected are not included

J - Estimated value; analyte concentration was less than the limit of quantification

U - Analyte was not detected.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

MCL - Maximum Contaminant Level

PCL - Protective Concentration Level

Table 2-4: Depth to Water and Shallow Zone Saturation Thickness - June 2016

1,4-Dioxane (8270D-SIM)													
1,4-DIOXANE	ug/L	9.1	NA	<1 U	220	NA	0.587 J	NA	<1 U	NA	6.52	NA	NA

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

1,4-Dioxane (8270D-SIM)												
1,4-DIOXANE	ug/L	9.1	<1 U	<1 U	<1 U	<1 U	<1 U	<1 U	<1 U	<1 U	<1 U	<1 U

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location ID: / Sample Date:	Units	MCL/ PCL	18WW02-062216 6/22/2016	18WW02F-062216 6/22/2016	18WW03-061416 6/14/2016	18WW03F-061416 6/14/2016	18WW06-062016 6/20/2016	18WW06FD-062016 6/20/2016	18WW08-062016 6/20/2016	18WW09-062016 6/20/2016	18WW16-061616 6/16/2016	18WW16F-061616 6/16/2016	18WW17-062116 6/21/2016
1,4-Dioxane (8270D-SIM)													
1,4-DIOXANE	ug/L	9.1	<1 U	NA	<1 U	NA	<1 U	<1 U	<1 UJ	<1 UJ	NA	NA	NA

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

1,4-Dioxane (8270D-SIM)													
1,4-DIOXANE	ug/L	9.1	<1 U	NA	NA	NA	NA	<1 UJ	<1 U	NA	NA	<1 U	NA

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

1,4-Dioxane (8270D-SIM)													
1,4-DIOXANE	ug/L	9.1	7.14	5.74	<1 U	<1 U	NA	NA	NA	<1 U	NA	NA	NA

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

1,4-DIOXANE	ug/L	9.1	NA	<1 U	NA	7.58	NA	0.819 J	13.4	0.649 J	1.77 J	<1 U	NA

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

1,4-Dioxane (8270D-SIM)													
1,4-DIOXANE	ug/L	9.1	NA	NA	412	390	18	NA	<1 U	NA	NA	NA	NA

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Table 2-15: LHAAP-18/24 Semi-Annual Groundwater Sampling Results - June 2016

Location ID: / Sample Date:	Units	MCL/ PCL	MW21-062216 6/22/2016	MW22-060816 6/8/2016	MW23-061716 6/17/2016
1,4-Dioxane (8270D-SIM)					
1,4-DIOXANE	ug/L	9.1	1.55 J	NA	NA

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Table 2-16: Chemicals Contributing to Carcinogenic Risk in Wilcox Formation Groundwater

Chemical	Shallow Zone ELCR [a]	Shallow Zone EPC [a] (µg/L)	Shallow Zone Well	Recent Maximum in Wilcox Formation (µg/L)	Date	Well	MCL (µg/L)	TTRP PCL (µg/L)	Retained as a CoC?
Methylene chloride	4.0×10^{-1}	7,300,000	MW-2	746	06/24/2016	18CPTMW01SW	5	—	Yes, 1
Trichloroethene	4.1×10^{-2}	210,000	MW-2	15,900	06/07/2016	MW-14B	5	—	Yes, 1
2,3,7,8-TCDD	1.1×10^{-5}	530	95 UCL	—	—		3.0×10^{-5}	—	No, 2
4,4'-DDD	1.3×10^{-6}	59	MW-2	—	—		—	3.8	No, 2
Benzene[3]	—	—	—	6.13	06/08/2016	18CPTMW03SW	5	—	Yes, 1
1,1,2-Trichloroethane[3]	—	—	—	0.858	06/15/2016	18CPTMW23	5	—	No, 5
Vinyl Chloride[3]	—	—	—	8.97	06/08/2016	18CPTMW08SW	2	—	Yes, 1
1,4-Dioxane[3]	—	61.7	95 UCL[c]	412	06/07/16	MW-14B	—	9.1	Yes, 1
Chloroform	4.2×10^{-5}	28	95 UCL	13.2	06/07/16	MW-14B	—	240	No, 2,5
Chemicals Retained on a Provisional Basis									
Tetrachloroethene	—	—	—	< 50	06/07/2016	MW-14B	5	—	Yes, 4
Bromodichloromethane[b]	2.3×10^{-6}	530	18WW09	< 40	06/07/16	MW-14B	—	15	Yes, 4

Notes and Abbreviations:

1. Identified as a COC since recent results are above the MCL or PCL and the compound is identified as a CoC in the Shallow Zone.
2. Combined Shallow Zone ELCR of Chemicals with no MCL is within acceptable range of 1×10^{-6} to 1×10^{-4}.
3. Included as contributing chemicals due to their frequency of detection above the MCL or PCL in recent sampling events.
4. Identified as a COC due to high reporting limit in Wilcox Formation well(s) and presence in Shallow Zone groundwater. Retained on a provisional basis.
5. Excluded as a COC as maximum concentration in Wilcox Formation is below MCL/PCL.

a. From Baseline Risk Assessment Table C-53 (Jacobs, 2002).
b. All other wells were < 15 ug/L (the majority were below detection). Bromodichloromethane will be re-evaluated when data with lower reporting limit are obtained.
c. Using ProUCL for the results of samples collected in June 2016.

95 UCL indicates that the EPC was calculated rather than the maximum concentration at a specific well.

CoC	contaminant of concern
ELCR	excess lifetime cancer risk
EPC	exposure point concentration
TRRP PCL	Texas Risk Reduction Program Protective Concentration Level (Tier 1 Groundwater Residential)
MCL	maximum contaminant level from the Safe Drinking Water Act
µg/L	micrograms per liter
B	Sample collected from the bottom of well screen

Table 2-17: Chemicals Contributing to Toxicity in Wilcox Formation Groundwater

Chemical	SZ HQ [a]	SZ EPCz [a] (µg/L)	SZ Well	Revised Wilcox Frmn HQ	Recent Wilcox Frmn Maximum (µg/L)	Date	Well	MCL (µg/L)	TRRP PCL (µg/L)	Retained as a CoC?
Methylene chloride	1600	7,300,000	MW-2	0.16	746	06/24/2016	18CPTMW01 SW	5		Yes, 1

Antimony	8.1	333	95 UCL[b]	<0.00002	<0.001	June 2016	All Wells	6		No, 4
Arsenic[6]	—	—	—	c	17.3	06/24/16	18CPTMW01 SW	10		Yes, 1
Barium	0.84	6,000	MW-1	0.22	1,560	06/14/14	C-03	2,000		Yes, 3
Chromium	0.12	18,000	MW-1	0.000063	9.5	06/14/16	18CPTMW04 SW	100		No, 4
Cobalt	0.14	280	MW-1	0.005	9.64	06/24/16	18CPTMW12 SW		240	No, 4
Manganese	1.7	8,270	MW-1	0.38	1,850	06/14/16	C-03		1,100*	No, 6
Nickel	4.7	9,600	MW-1	0.0036	7.44 J	06/24/16	18CPTMW12 SW		490	No, 4
Silver	0.94	480	MW-1	< 0.002	< 1	June 2016	All Wells		120	No, 4
Thallium	0.47	3.7	MW-2	< 0.025	< 0.200	June 2016	All Wells	2		No, 4
Chemicals Retained on a Provisional Basis										
1,3,5-Trinitrobenzene	0.33	1,000	MW-2		No Recent Data				730	Yes, 2

Notes and Abbreviations:

1. Identified as a COC since Recent Results are above the MCL or PCL.
2. Identified as COC since Shallow Zone hazard quotient (HQ) is > 0.1 and no recent data available.
3. Retained as a COC since Revised Wilcox Formation HQ > 0.1 and sum of HQs may exceed 1.0.
4. Excluded since Revised Wilcox Formation HQ < 0. 1 using recent maximum concentration and chemical concentration is < PCL.
5. Excluded as a COC as maximum concentration in Wilcox Formation is below MCL/PCL., and pattern of detections does not indicate association with site contamination.
6. Excluded because maximum concentrations of recent results are below the background 95%UTL.

a. From Baseline Risk Assessment Table C-50 (Jacobs, 2002).
b. Using ProUCL for the results of samples collected in June 2016.

95 UCL indicates that the EPC was calculated rather than the maximum concentration at a specific well.

SZ	Shallow Zone
CoC	contaminant of concern
EPC	exposure point concentration
HQ	hazard quotient
MCL	maximum contaminant level from the Safe Drinking Water Act
UCL	upper confidence limit
TRRP PCL	Texas Risk Reduction Program Protective Concentration Level (Tier 1 Groundwater Residential)
µg/L	micrograms per liter
B	Sample collected from the bottom of well screen
T	Sample collected from top of well screen

* 95% UTL value from Final Evaluation of Perimeter Well Data for Use as Groundwater Background (Shaw, 2007) for Manganese is 7,820 µg/L, which is above the TRRP Tier 1 Groundwater Residential PCL thus the background value will be considered the Cleanup Level for Manganese.

3 REMEDIAL ACTION OBJECTIVES AND CLEANUP LEVELS

This section identifies the LHAAP-18/24 RAOs (**Section 3.1**), potential chemical-, location- and action-specific ARARs (**Section 3.2**), and cleanup levels (**Section 3.3**). The RAOs identify the general goals or endpoints that the remediation will accomplish, while the cleanup levels identify specific cleanup standards for each medium of concern based on risk or ARARs. The cleanup levels may be applied to individual contaminants.

3.1 Remedial Action Objectives

RAOs are established to protect human health and the environment while also meeting ARARs. The identification of RAOs must consider the environmental impacts at the site and the receptors that are affected. The CSM (**Section 2.5**) identifies the primary environmental issue at LHAAP-18/24 as groundwater posing an unacceptable risk or hazard to the hypothetical future maintenance worker due to contamination by VOCs (primarily MC, TCE, chloroform, and cis-1,2-DCE), the anion perchlorate, 1,4-dioxane, and metals (primarily barium, chromium, and nickel). Although the soil is not considered a medium of concern with respect to human health or ecological risk, unsaturated soils have the potential to serve as an ongoing source of contaminants to groundwater. Additionally, the implied presence of residual DNAPL within the saturated soil is considered a secondary source of contaminants to groundwater. Therefore, the RAOs will address these three media: unsaturated soil, groundwater, and saturated soil (secondary source areas w/ DNAPL).

The future use of the entire LHAAP facility is as a National Wildlife Refuge. The RAOs for LHAAP-18/24, which address contamination associated with the media at the site and take into account the future uses of LHAAP streams, land, and groundwater are as shown below by medium.

Groundwater:

- Prevent human exposure to the groundwater contaminated with VOCs, metals, 1,4-dioxane, and perchlorate above cleanup levels
- Prevent or minimize contaminated groundwater from discharging to surface water above cleanup levels
- Prevent or minimize further migration of the contaminant plume
- Return groundwater to its potential beneficial uses as drinking water, where practicable.

Source Materials:

- Prevent or minimize further migration of contaminants from source materials in the saturated and unsaturated zones to groundwater.

The above RAOs recognize USEPA's policy to return all groundwater to beneficial uses, based on the non-binding programmatic expectation in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) and are consistent with the NCP regulations requiring the lead agency, the U.S. Army in this case, to establish RAOs specifying contaminants and media of concern, potential exposure pathways, and remediation goals.

3.2 Applicable or Relevant and Appropriate Requirements

The NCP, 40 Code of Federal Regulations (CFR) 300.430(f)(1)(ii)(B) states that on-site remedial actions selected in a ROD must attain those ARARs that are identified at the time of the ROD signature, or provide grounds for invoking a waiver under CFR 300.430(f)(1)(ii)(C). This section provides a preliminary identification and evaluation of potential federal and State of Texas chemical-, location-, and action-specific ARARs for the remediation of LHAAP-18/24 under CERCLA.

3.2.1 Definitions and Methods

Applicable requirements are those cleanup standards, standards of control, and other substantive environmental protection requirements, criteria, or limitations promulgated under federal or state environmental or facility siting laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site (40 CFR 300.5).

Relevant and appropriate requirements means those cleanup standards, standards of control, and other substantive requirements, criteria, or limitations promulgated under federal environmental or state environmental or facility siting laws that, while not “applicable” to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site. Only those state standards that are identified in a timely manner and are more stringent than federal requirements may be relevant and appropriate.

To qualify as a state ARAR mandating cleanup standards under 40 CFR 300.400(g)(4) of the NCP, a state requirement must be (1) promulgated (of general applicability and legally enforceable), (2) an environmental or facility siting law or regulation, (3) more stringent than federal requirement, (4) identified by the state in a timely manner, and (5) consistently applied throughout the state.

ARARs are generally divided into chemical-, location-, and action-specific requirements. Chemical-specific ARARs are usually promulgated health- or risk-based numerical values or methods used to determine acceptable concentrations of chemicals that may be found in, or discharged to, the environment. Location-specific ARARs restrict actions or contaminant concentrations in certain environmentally sensitive areas. Action-specific ARARs are usually technology- or activity-based requirements or limitations on actions taken with respect to hazardous wastes.

An on-site action need not comply with administrative parts of requirements identified as ARARs. According to USEPA guidance (USEPA, 1988a), administrative requirements are mechanisms that facilitate the implementation of the related substantive requirements of a statute or regulation (e.g., approval of or consultation with administrative bodies, documentation, permit issuance, reporting, and record keeping).

The NCP at 40 CFR 300.400(e)(1) exempts on-site actions from having to obtain federal, state, or local permits and defines “on-site” as meaning “the aerial extent of contamination and all suitable areas in very close proximity to the contamination necessary for implementation of the response action.” However, on-site actions must still be in compliance with any substantive permit requirements. CERCLA 121(e)(1) and 55 Federal Register (FR) 8666 state "CERCLA actions should not be delayed by time-consuming and duplicative administrative requirements

such as permitting, although remedies should achieve the substantive standards of applicable or relevant and appropriate laws."

Off-site actions must not only comply with requirements that are legally applicable, but they must comply with both the substantive and the administrative parts of those requirements. Permits, if required, must be obtained for all remedial activities conducted off site, (40 CFR 300.400(e)(2)). Statutory waivers of ARARs (40 CFR 300.430(f)(1)(ii)(C)) may not be used for off-site actions. CERCLA section 121(d) requires on-site Superfund remedial actions to comply with Federal, and more stringent State, environmental requirements that are determined to be ARARs; and even though requirements for off-site actions are not ARARs, they must be complied with.

The USEPA has noted in its CERCLA guidance that if attainment of a numerical value that is a potential chemical-specific ARAR is impossible because the background level of the chemical subject to CERCLA authority is higher than that of the potential ARAR, the numeric criterion would not be considered an ARAR (USEPA, 1991).

ARARs include only federal or more stringent state environmental laws and regulations that are identified in a timely manner and do not include occupational safety regulations. The USEPA requires compliance with the Occupational Safety and Health Administration (OSHA) standards and other worker protection requirements under Section 300.150 of the NCP, not through the ARARs process. Therefore, none of the promulgated OSHA regulations (e.g., 29 CFR 1926, 29 CFR 1910) are addressed here as ARARs.

In addition to ARARs, 40 CFR 300.400(g)(3) states that federal or state non-promulgated advisories or guidance may be identified as to-be-considered (TBC) guidance for contaminants, conditions, and/or actions at the site. TBCs consist of criteria, advisories, and guidance. TBCs are not ARARs because they are neither promulgated nor enforceable. TBCs may be used to interpret ARARs and to determine preliminary cleanup levels when ARARs do not exist for particular contaminants or are not sufficiently protective to develop cleanup levels. TBCs, such as guidance or policy documents, developed to implement regulations may be considered and used where necessary to ensure protectiveness. No TBCs were identified for LHAAP-18/24.

Potential chemical-specific requirements are discussed in **Section 3.2.2**; **Table 3-1** includes a narrative listing of chemical-specific ARARs for LHAAP-18/24. Potential location-specific ARARs were not identified at LHAAP-18/24. Potential action-specific ARARs are discussed in **Section 3.2.4** and are listed and grouped by component action in **Table 3-2**. **Table 3-3** provides a listing of non-ARARs. However, the procedural requirements of those non-ARARs will be adhered to during remedy implementation at LHAAP-18/24.

3.2.2 Potential Chemical Specific ARARs

This section identifies the potential chemical-specific ARARs that apply to surface/subsurface soils, air and groundwater at LHAAP-18/24. These ARARs are summarized in **Table 3-1**.

3.2.2.1 Potential Chemical Specific ARARs for Surface Water

Section 121(d)(2) of CERCLA states that every remedial action shall require a level of control which at least attains surface water quality criteria established under Sections 304 or 303 of the Clean Water Act of 1972 (CWA), where relevant and appropriate. Therefore, surface water

quality criteria are ARARs if there is a remedial action that affects surface water, and measures will be implemented during construction to prevent off-site migration of contaminants to surface waters. In the event of remedy failure resulting in or potentially resulting in a release to surface water, 40 CFR 122, 125, 129, 130, and 131 and 30 Texas Administrative Code (TAC) 307.1, 307.2, 307.3, 307.4, 307.5(a) and (b), 307.6, 307.7, 307.8 and 307.9 are considered potential future ARARs.

For discharge of treated groundwater to surface water, the Texas Surface Water Quality Standards (30 TAC 307.1 through 307.10) are considered relevant and appropriate. The interim Record of Decision for LHAAP-18/24 established effluent discharge criteria for treated groundwater. These criteria are considered the cleanup levels for extracted groundwater at LHAAP-18/24. The discharge criteria for the CoCs will be re-evaluated based on the most current TCEQ surface water quality criteria.

3.2.2.2 Potential Chemical Specific ARARs for Groundwater

The baseline risk assessment (Jacobs, 2002) indicated that the contaminated groundwater at LHAAP-18/24 presented unacceptable risk and hazard to a hypothetical future maintenance worker. The chemical-specific ARAR is the attainment of the SDWA MCL for all groundwater CoCs and by-product contaminants. In the absence of federal drinking water standards, cleanup levels will be based on TRRP Tier 1 Groundwater Residential PCLs.

3.2.3 Potential Location Specific ARARs

No location specific ARARs are identified for LHAAP-18/24. Some procedural considerations that are location specific but are not considered ARARs are discussed in **Section 3.2.5**.

3.2.4 Potential Action Specific ARARs

Action-specific ARARs include operation, performance and design requirements or limitations based on the waste types, media, and remedial activities. This section provides a preliminary identification and evaluation of potential federal and state of Texas action-specific ARARs for the proposed remediation of LHAAP-18/24.

Pursuant to USEPA guidance, there are no action-specific ARARs for the required no action alternative (USEPA, 1991). The action-specific ARARs for the activities common to the remedial action to be conducted at LHAAP-18/24 are discussed in **Section 3.2.4.1** below. All potential action-specific ARARs are listed in **Table 3-2** and are grouped by component action.

Each of the proposed remedial action alternatives will involve several of the following activities: waste generation, characterization, management, storage, and disposal activities; well construction; and water treatment. Action-specific ARARs are discussed here for the activities common to the remedial activities to be proposed for LHAAP-18/24.

3.2.4.1 Site Preparation, Construction, and Excavation Activities

Certain on-site preparation, construction, and/or excavation activities will be necessary under all remediation actions to prepare the site for remediation, including soil-moving or site-grading activities. Control of fugitive emissions and storm water runoff during implementation of these activities will be required.

Airborne particulate matter resulting from construction or excavation activities is subject to the fugitive dust and opacity limits listed in 30 TAC 111, Subchapter A. No person may cause, suffer, allow, or permit visible emissions from any source to exceed an opacity of 30 percent for any 6-minute period (30 TAC 111.111[a]). Reasonable precautions must also be taken to achieve maximum control of dust to the extent practicable, including the application of water or suitable chemicals or the complete covering of materials (30 TAC 111.143 and 30 TAC 111.145).

Texas has also promulgated general nuisance rules for air contaminants mandating that no person shall discharge from any source whatsoever one or more air contaminants, or combinations thereof, in such concentration and of such duration as are or may tend to be injurious to or to adversely affect human health or welfare, animal life, vegetation, or property, or as to interfere with the normal use and enjoyment of animal life, vegetation, or property (30 TAC 101.4).

Storm water discharges from construction activities that disturb equal to or greater than one acre of land must comply with the substantive requirements of a USEPA National Pollutant Discharge Elimination System (NPDES) general permit (40 CFR 122.26; 30 TAC 205, Subchapter A; and 30 TAC 308.121), depending on the amount of acreage disturbed. Substantive requirements include implementation of good construction management techniques; phasing of large construction projects; minimal clearing; and sediment, erosion, structural, and vegetative controls to mitigate runoff and ensure that discharges meet required parameters.

3.2.4.2 Waste Generation, Characterization, Management, Storage, and Disposal Activities

The processes of monitoring, intercepting, or treating contaminated groundwater may generate a variety of primary and secondary waste streams (e.g., soil, personal protective equipment [PPE], and dewatering and decontamination fluids). These waste streams are expected to be non-hazardous waste. All solid waste (defined as any solid, liquid, semisolid, or contained gaseous material intended for discard [40 CFR 261.2]) generated during remedial activities must be appropriately characterized to determine whether it contains RCRA hazardous waste (40 CFR 262.11; 30 TAC 335.62; 30 TAC 335.503[a][4]; 30 TAC 335.504). All wastes must be managed, stored, treated (if necessary), and disposed of in accordance with the ARARs for waste management listed in **Table 3-2** for the particular type of waste stream or contaminants in the waste.

Excavated environmental media including soil excavated during the installation of monitoring/ extraction wells or to remove contaminated soil would be sent off site for disposal or, in the case of non-hazardous trenching or well construction soil, redeposited within the area of contamination (AOC). The USEPA defines “onsite” as the areal extent of contamination and all suitable areas in close proximity to the contamination necessary for the implementation of the CERCLA response action and notes that such contamination may contain varying types and concentrations of hazardous substances (Volume 53FR page 51444; 55 FR 8758). Portions of the soil generated from remedial activities at LHAAP-18/24 could be hazardous. ARARs for the management of such media at the site of generation (i.e., within the AOC) are listed in **Table 3-2**.

The USEPA has stated that excavation and redeposition of contaminated soil within an AOC does not constitute “generation”; therefore, the requirements of 40 CFR 262.11 and 268.7 to characterize generated wastes are not applicable (Office of Solid Waste and Emergency

Response Directive 9441.1992[16], June 11, 1992). Consolidation of waste between AOCs for treatment or disposal, however, or excavation and treatment with subsequent disposal in the same AOC or off-site disposal constitute "placement." In these situations, RCRA Subtitle C requirements for the generation, handling, treatment, and disposal of such wastes are applicable if the waste/media is determined to contain RCRA hazardous waste (55 FR 8758) (USEPA, 1990).

3.2.4.3 Water Treatment

Contaminated groundwater and wastewaters collected during groundwater extraction, well drilling, or decontamination activities could be transported to the existing groundwater treatment plant constructed as a component of the previous IRA at LHAAP-18/24 and would subsequently be discharged in compliance with the CWA outfall limits for the plant as listed in the interim ROD. To assure compliance with the treatment plant's discharge limits, the incoming water must meet the design criteria for the plant such as air to water ratio for the air stripper. On-site wastewater treatment units (as defined in 40 CFR 260.10) that are part of a wastewater treatment plant that is subject to regulation under Section 402 or Section 307(b) of the CWA are not subject to RCRA Subtitle C hazardous waste management standards (40 CFR 270.1[c][2][v]; 40 CFR 264.1[g][6]; 30 TAC 335.42[d][1]). The USEPA has clarified that this exemption applies to all tanks, conveyance systems, and ancillary equipment, including piping and transfer trucks, associated with the wastewater treatment unit (53 FR 34079, September 2, 1988).

3.2.4.4 Well Construction

All of the proposed alternatives, other than the no action alternative, may involve the placement, use, or eventual plugging and abandonment of some type of groundwater monitoring, injection, and/or extraction wells, either for in situ treatment or extraction of the contaminated groundwater or for long-term monitoring (LTM) of the groundwater. Available standards for well construction and plugging/abandonment would provide ARARs for such actions and include 30 TAC 331, Subchapters A, C, and H.

Texas has promulgated technical requirements in Chapter 76 of Title 16 of the TAC applicable to construction, operation, and plugging/abandonment of water wells. In particular, 16 TAC 76.1000 (Locations and Standards of Completion for Wells), 16 TAC 76.1002 (Standards for Wells Producing Undesirable Water or Constituents) (LHAAP-18/24 contaminated groundwater could be considered "undesirable water" defined pursuant to Section 76.10[36] as "water that is injurious to human health and the environment or water that can cause pollution to land or other waters"), 16 TAC 76.1004 (Standards for Capping and Plugging of Wells and Plugging Wells that Penetrate Undesirable Water or Constituent Zones), and 16 TAC 76.1008 (Pump Installation) may provide ARARs for the placement, construction, and eventual plugging/abandonment of groundwater injection or extraction wells or the placement and long-term operation of groundwater monitoring wells for proposed groundwater remedial strategies.

3.2.5 Non-ARAR Procedural Considerations

Certain relevant requirements that are not identified as ARARs are included in this section and in **Table 3-3**.

3.2.5.1 Threatened and Endangered Species

No federally endangered species are known to occur on the installation. There are 22 animal species that could potentially be present on or near LHAAP that appear on federal or state threatened species lists. The historic details regarding the number and date of species sightings are presented in the Caddo Lake Institute report (CLI, 1995). Of the 22 animal species that could potentially be present, information from the U.S. Fish and Wildlife Service (USFWS), and the Texas Department of Parks and Wildlife in 2003 identified the following list of threatened species and ecological communities of concern that are known or suspected to occur in the vicinity of LHAAP (species that have been confirmed are listed in italics) (Shaw, 2007b).

- Federal Listed Threatened Species:
    - *Bald Eagle*
    - Louisiana Black Bear
- State Listed Threatened Species:
    - Louisiana Black Bear
    - *Rafinesque's Big-Eared Bat*
    - *Alligator Snapping Turtle*
    - *Timber Rattlesnake*
    - Bluehead Shiner
- State Species of Concern:
    - Southern Lady's Slipper
- State Special Features/Natural Communities/Managed Areas:
    - Colonial Waterbird Rookeries
    - Bald Cypress-Water Tupelo Series
    - Shortleaf Pine-Oak Series
    - Water Oak-Willow Oak Series
    - Caddo Lake State Park

Some conflicting evidence is available regarding the potential presence of the Timber Rattlesnake at Longhorn. This State-listed species is described in historical site documents as being confirmed present on the site, but there is no recent documented evidence of this species being present on site (Shaw, 2007b). Therefore, it is assumed that the Timber Rattlesnake is potentially present, along with the Alligator Snapping Turtle, as well as the Bald Eagle and the Rafinesque's Big-Eared Bat. Timber rattlesnakes prefer moist lowland forests and hilly woodlands or thickets near permanent water sources such as rivers, lakes, ponds, streams and swamps where tree stumps, logs and branches provide refuge. Alligator snapping turtles prefer deep waters of ponds, canals, lakes, streams, or swamps where they spend most of their time concealed by mud. Bald eagles in Texas may either represent breeding populations or wintering populations, and tend to roost on large lakes and rivers with tall trees for nesting and

unobstructed flight paths to food sources (typically fish). Although Rafinesque's big-eared bats roost in cave entrances, abandoned buildings and under bridges, the preferred roosting sites for these bats are large, dead, hollow trees. Timber Rattlesnakes have not been observed at the installation by resident wildlife experts, and large water bodies with deep pools required by alligator snapping turtles are not present at this site. Common bat roosting locations, such as dead tree snags and abandoned buildings are not features at this site, and no bald eagle nests are documented as being present in this area. Furthermore, although the site may be used occasionally by bald eagles or Rafinesque's big-eared bats during migration or as part of a foraging territory, this site is too small (34.5 acres) for regular exposure to occur for these species, which have home ranges of hundreds of acres. The potential for these threatened species to be present at LHAAP-18/24 is low. Thus, based on current information, potential remedial action alternatives are not expected to harm any federal- or state-listed threatened or endangered species or their critical habitat. Substantive requirements of the federal Endangered Species Act (16 U.S. Code (USC) 1531 et seq.), the federal Bald Eagle Protection Act (16 USC 668 et seq.), and the Texas Resource Protection Act (31 TAC 69, Subchapters A and B, and 31 TAC 65, Subchapter G) while not ARARs, will be complied of during implementation of proposed remedial alternatives. These non-ARARs are included in **Table 3-3** in the event that such threatened and endangered species/habitats are identified at LHAAP-18/24 in the future.

3.2.5.2 Waste Generation, Characterization, Management, Storage, and Disposal Activities

Hazardous waste requirements such as manifesting for off-site disposal (40 CFR 262.20) and planning/implementing off-site response action (40 CFR 300.440) will be complied with even though they are not considered an ARAR. Regulations associated with off-site treatment, storage, and disposal facilities (TSDF) that accept hazardous waste from the site are not considered ARARs, although the off-site TSDF must comply with waste characterization (40 CFR 264.13 and 268.7), land disposal requirements (40 CFR 268), and closure requirements (40CFR 264.111 & 264.178). The substantive requirements for hazardous waste storage in on site containers will be complied with in accordance with 40 CFR 264.171.

Table 3-1: Potential Chemical-Specific ARARs

Citation	Activity or Prerequisite/Status	Requirement
Groundwater		
Federal Safe Drinking Water Act MCLs 40 CFR 141	Applicable to drinking water—relevant and appropriate for water that could potentially be used for human consumption.	Must not exceed MCLs, if relevant and appropriate, for water designated as a current or potential source of drinking water. See Tables 2-1 and 2-2 for specific numeric criteria.
Surface Water		
Texas Surface Water Quality Criteria 30 TAC 307.1 through 307.10	Applicable to industrial groundwater—relevant and appropriate to meet Texas surface water quality criteria	Interim Record of Decision effluent discharge limits. The discharge criteria for the COCs will be re-evaluated based on most current TCEQ standards.

Abbreviations:

ARAR	applicable or relevant and appropriate requirement	TAC	Texas Administrative Code
GWP	groundwater protection	TCEQ	Texas Commission on Environmental Quality
MCL	maximum contaminant level	PCL	Texas Residential Groundwater Protective Concentration Levels

Table 3-2: Potential Action-Specific ARARs

Citation	Activity or Prerequisite/Status	Requirement
General Site Preparation, Construction, and Excavation Activities		
Air Contaminants – General Nuisance Rules 30 TAC 101.4	Emissions of air contaminants—applicable.	No person shall discharge from any source whatsoever one or more air contaminants or combinations thereof, in such concentration and of such duration as are or may tend to be injurious to or to adversely affect human health or welfare, animal life, vegetation, or property, or as to interfere with the normal use and enjoyment of animal life, vegetation, or property.
Opacity Standard 30 TAC 111.111(a)(8)(A)	Fugitive emissions from land-disturbing activities (e.g., excavation, construction)—applicable.	Visible emissions shall not be permitted to exceed opacity of 30% for any 6-minute period from any source.
Fugitive Particulate Matter Standard 30 TAC 111.145	Fugitive emissions from land-disturbing activities (e.g., excavation, construction)—applicable.	No person may cause, suffer, allow, or permit a structure, road, street, alley or parking area to be constructed, altered, repaired, or demolished, or land to be cleared without taking at least the following precautions to achieve control of dust emissions: • Use of water or of suitable oil or chemicals for control of dust in the demolition of structures, in construction operations, in work performed on a road, street, alley, or parking area, or in the clearing of land; and • Use of adequate methods to prevent airborne particulate matter during sandblasting of structures or similar operations.
Storm water Runoff Controls 40 CFR 122.26; 30 TAC 205, Subchapter A; 30 TAC 308.121	Storm water discharges associated with construction activities—applicable to disturbances of equal to or greater than 1 acre of land.	Good construction management techniques, phasing of construction projects, minimal clearing, and sediment, erosion, structural, and vegetative controls shall be implemented to mitigate storm water run-on/runoff.
Waste Generation, Management, and Storage		
Characterization of Solid Waste 40 CFR 262.11 30 TAC 335.62 30 TAC 335.504 30 TAC 335.503(a)(4)	Generation of solid waste, as defined in 30 TAC 335.1—applicable.	Must determine whether the generated solid waste is RCRA hazardous waste by using prescribed testing methods or applying generator knowledge based on information regarding material or process used. If the waste is determined to be hazardous, it must be managed in accordance with 40 CFR 262–268. After making the hazardous waste determination as required, if the waste is determined to be nonhazardous, the generator shall then classify the waste as Class 1, Class 2, or Class 3 (as defined in Section 335.505 through Section 335.507) using one or more of the methods listed in Section 335.503(a)(4) and Section 335.508 and manage the waste in accordance with the requirements of Chapter 335 of the TAC for industrial solid waste.

Table 3-2: Potential Action-Specific ARARs

Citation	Activity or Prerequisite/Status	Requirement
Requirements for Temporary Storage of Hazardous Waste in Accumulation Areas 40 CFR 262.34(a) and (c)(1) 30 TAC 335.69(a) and (d)	On-site accumulation of 55 gallons or less of RCRA hazardous waste for 90 days or less at or near the point of generation—applicable if hazardous waste is generated (e.g., PPE) and stored in an accumulation area.	A generator may accumulate hazardous waste at the facility provided that • Waste is placed in containers that comply with 40 CFR 264.171 to 264.173 (Subpart I); and • Container is marked with the words “hazardous waste”; or • Container may be marked with other words that identify the contents.
Characterization of Hazardous Waste 40 CFR 268.7 30 TAC 335.504(3) 30 TAC 335.509 30 TAC 335.511	Generation of a RCRA hazardous waste for treatment, storage, or disposal—applicable if hazardous waste is generated (e.g., PPE).	Must obtain a detailed chemical and physical analysis of a representative sample of the waste(s) that at a minimum contains all the information that must be known to treat, store, or dispose of the waste in accordance with 40 CFR 264 and 268. Must also determine whether the waste is restricted from land disposal under 40 CFR 268 et seq. by testing in accordance with prescribed methods or use of generator knowledge of waste.
Well Construction		
Well Construction Standards—Monitoring or Injection Wells 16 TAC 76.1000	Construction of water wells—applicable to construction of new monitoring or injection wells, if needed.	Wells shall be completed in accordance with the technical requirements of Section 76.1000, as appropriate.
Well Construction Standards—Extraction Wells 16 TAC 76.1000(a) and (c) through (h) 16 TAC 76.1002(a) through (c) 16 TAC 76.1008(a) through (c)	Construction of water wells—applicable to construction of extraction (recovery) wells.	Wells shall be completed in accordance with the technical requirements of Section 76.1000, as appropriate. Water wells completed to produce undesirable water shall be cased to prevent the mixing of water or constituent zones. The annular space between the casing and the wall of the borehole shall be pressure grouted with cement or bentonite grout to the land surface. Bentonite grout may not be used if a water zone contains chloride water above 1500 ppm or if hydrocarbons are present. Wells producing undesirable water or constituents shall be completed in such a manner that will not allow undesirable fluids to flow onto the land surface. During installation of a water well pump, installer shall make a reasonable effort to maintain integrity of groundwater and to prevent contamination by elevating the pump column and fittings, or by other means suitable under the circumstances. Pump shall be constructed so that no unprotected openings into the interior of the pump or well casing exist.

Table 3-2: Potential Action-Specific ARARs

Citation	Activity or Prerequisite/Status	Requirement
Class V Injection Wells 30 TAC 331, Subchapter A, C, and H	Installation, operation, and closure of injection wells for in situ chemical oxidation fall in the category of Class V Injection Wells – relevant and appropriate.	Injection wells shall be constructed to the required specifications for isolation casing, surface completion, prevention of commingling, and confinement of undesirable groundwater to its zone of origin. Closure shall be accomplished by removing all of the removable casing and the entire well shall be pressure filled via a tremie pipe with cement from bottom to the land surface, or closure shall be performed by the alternative method for Class V Wells completed in zones of undesirable groundwater. Groundwater concentrations at time of well closure will determine the appropriate method of abandonment.
Treatment/Disposal		
Disposal of Wastewater (e.g., contaminated groundwater, dewatering fluids, decontamination liquids) 40 CFR 268.1(c)(4)(i) 30 TAC 335.431(c)	RCRA-restricted characteristically hazardous waste intended for disposal—applicable if extracted groundwater is determined to be RCRA characteristically hazardous.	Disposal is not prohibited if such wastes are managed in a treatment system subject to regulation under Section 402 of the CWA that subsequently discharges to waters of the United States.
Closure		
Standards for Plugging Wells that Penetrate Undesirable Water or Constituent Zones 16 TAC 76.1004(a) through (c)	Plugging and abandonment of wells—applicable to plugging and closure of monitoring and/or extraction wells.	If a well is abandoned, all removable casing shall be removed and the entire well pressure filled via a tremie pipe with cement from bottom up to the land surface. In lieu of this procedure, the well shall be pressure-filled via a tremie tube with bentonite grout of a minimum 9.1 lb/gal weight followed by a cement plug extending from land surface to a depth of not less than 2 feet. Undesirable water or constituents or the freshwater zone(s) shall be isolated with cement plugs.

Table 3-3: Non-ARAR Procedural Considerations

Resource/Citation	Activity or Prerequisite Status	Requirement
Protection of Threatened and Endangered Species (as listed in Table 3-5) Endangered Species Act (16 USC 1531 et seq.); 50 CFR 402; Bald Eagle Protection Act (16 USC 668 et seq.); Texas Resource Protection Act, 31 TAC 69 Subchapters A and B, and 31 TAC 65 Subchapter G	Activities that may adversely impact any state- or federally-listed, threatened or endangered species or their habitat—applicable if such species and/or habitats are impacted	Actions that jeopardize the existence of a listed species or result in the destruction or adverse modification of critical habitat must be avoided, or reasonable and prudent mitigation measures must be taken. No person may take, possess, propagate, transport, export, sell or offer for sale, or ship any species of fish, wildlife, or native plant listed by the Texas Parks and Wildlife Department as endangered or threatened. The Department shall actively seek full restitution for and/or restoration of such a native plant, fish, or wildlife, or habitat loss occurring as a result of human activities.
National Oil and Hazardous Substances Pollution Contingency Plan 0 CFR 300.440	Procedure for planning and implementing off-site response actions.	USEPA will determine the acceptability under the selection of any facility selected for the treatment, storage, or disposal of CERCLA waste.
Management of RCRA Hazardous Waters—Wastewater Treatment Unit Exclusion 40 CFR 264.1(g)(6) 40 CFR 270.1(c)(2) 30 TAC 335.41(d)(1)	Treatment/disposal of wastewater containing RCRA hazardous waste—applicable to management of contaminated groundwater if it is determined to contain RCRA characteristically hazardous waste.	On-site wastewater treatment units, as defined in 40 CFR 260.10, that are part of a wastewater treatment facility subject to regulation under Section 402 or Section 307(b) of the CWA are excluded from the requirements of RCRA Subtitle C (Note: USEPA has clarified that this exemption applies to all tank systems, conveyance systems, and ancillary equipment, including transfer trucks, associated with the wastewater treatment unit [53 FR 34079, September 2, 1988]).
Requirements for the Use and Management of Containers 40 CFR 264.171–264.173 30 TAC 335.69(e) 30 TAC 335.152(a)(7)	On-site storage/treatment of RCRA hazardous waste in containers for greater than 90 days—applicable if hazardous waste is generated (e.g., PPE) and is stored in containers.	Design and operating standards of 40 CFR 264.175(c) and 40 CFR 264.171, 264.172, and 264.173(a) and (b) must be met for the use and management of hazardous waste in containers.
Requirements for Closure of a RCRA Container Storage Area 40 CFR 264.111 40 CFR 264.178 30 TAC 335.152(a)(5) 30 TAC 335.152(a)(7)	Closure of a RCRA-permitted container storage area—applicable if hazardous waste is generated (e.g., PPE) and is stored in containers.	Must close unit in a manner that • Minimizes the need for further maintenance; • Controls, minimizes, or eliminates, to the extent necessary to protect human health and the environment, post-closure escape of hazardous waste, hazardous constituents, leachate, contaminated runoff, or hazardous waste decomposition products to ground or surface waters or to the atmosphere; and • Complies with closure requirements of 40 CFR 178. All hazardous waste and residues must be removed from containment system. Remaining containers, liners, bases, and soil containing or contaminated with hazardous waste or residues must be decontaminated or removed.

4 IDENTIFICATION AND SCREENING OF TECHNOLOGIES AND PROCESS OPTIONS

The primary objective of identifying, screening, and evaluating potentially applicable technology types and process options for the LHAAP-18/24 is to identify an appropriate range of remedial technologies and process options to be developed into remediation alternatives. This screening process consists of a series of analytical steps that include the following:

- Identify volumes or areas of media of concern, and the associated CoCs (**Section 4.1**)
- Identify GRAs (**Section 4.2**)
- Identify and screen remedial technologies and process options (**Section 4.3**)
- Evaluate and select representative process options (**Section 4.4**)

These steps are outlined in the USEPA (RI)/FS guidance (USEPA, 1988b) and the NCP.

4.1 Contaminants and Media Quantities of Concern

Section 2.0 presents current site conditions at LHAAP-18/24. Based on available sampling data, groundwater at LHAAP-18/24 has been identified as the medium of concern because it poses an unacceptable carcinogenic risk and non-carcinogenic hazard to a hypothetical future maintenance worker. Soil has not been identified as a medium of concern for protection of human health and ecological risk; however, it was identified as a medium of potential concern for the protection of groundwater from potential cross-media transfer. The contamination can be summarized as follows:

- A plume of dissolved perchlorate contamination that exceeds the cleanup level exists under the entire site in the shallow zone with additional significant plume areas outside the LHAAP-18/24 footprint. The extent of the contamination is fairly well defined, with the perchlorate plume size in the Shallow Zone estimated at 67 acres (**Figure 1-9**) and in the Wilcox Formation at 21 acres (**Figure 1-10**). A Shallow Zone well, 18WW24, was installed in May 2014, just to the south of Harrison Bayou and north of MW-16. The perchlorate concentration in this well in June 2016 was 0.228 J µg/L. Another Shallow Zone well adjacent to Harrison Bayou, 18WW25 was installed and sampled in June 2016 and had a reported perchlorate concentration of < 0.2 µg/L. The concentrations in these two wells define the perchlorate plume to the north of MW-16 and 18CPTMW23, and to the northwest of 18CPTMW15. In May 2014, installation of monitoring well 18WW23 was attempted near C-01 to the south of 18CPTMW22 to determine extent of perchlorate in this area of the site. However, no groundwater was found and the Wilcox clay was encountered at approximately 12-13 ft bgs. Three soil samples were collected from the boring and the boring was plugged and abandoned. All three samples had perchlorate concentrations below the detection limit (< 2.4 µg/kg).
- A plume of dissolved MC contamination exceeding cleanup levels exists in the shallow zone and in the Wilcox Formation near the southern area of the UEP and to the northwest of the UEP inside the containment of LHAAP-18/24 (the ACD (west side) plume has very low MC concentrations). The extent of the contamination is known, and the size of the MC plume in

the Shallow Zone is approximately 7.3 acres (**Figure 1-13**) and 4.8 acres in the Wilcox Formation (**Figure 1-14**).

- A plume of dissolved TCE contamination exceeding the cleanup level exists in the shallow zone under the entire site with additional significant plume areas outside the LHAAP-18/24 footprint. The extent of the contamination is known, and the size of the TCE plume in the Shallow Zone is approximately 59 acres (**Figure 1-11**). The high TCE concentrations in shallow groundwater coincide with the two areas of MC contamination: MW-2 south of the former UEP and monitoring well 120 northwest of the former ACD. A Wilcox Formation dissolved TCE plume has an area of approximately 16.6 acres (**Figure 1-12**) and covers a large portion of the containment area with the highest concentration found in MW-14 in the former ACD area. The lateral extent of the contamination in the Wilcox Formation is known, however, determination of the vertical extent of contamination may require installation of additional deeper Wilcox wells during the design phase.
- A plume of dissolved 1,4-dioxane exceeding the cleanup level exists in the Shallow Zone in the ACD area and another plume is present to the south, in the area around MW-7. The extent of the contamination is known, and the size of the 1,4-dioxane plumes in the Shallow Zone is approximately 2.7 acres (**Figure 1-15**). A Wilcox Formation dissolved 1,4-dioxane plume has an area of approximately 1.2 acres (**Figure 1-16**) centered around MW-14 in the former ACD area.
- Isolated detections of metals in the shallow zone at concentrations exceeding the MCLs/PCLs occur across the site, but without the clear plume patterns exhibited by VOCs. The major metals in the Shallow Zone are arsenic, barium, and chromium. The other metals (manganese, cadmium, lead, and nickel) are not detected consistently. In the Wilcox Formation, sporadic detections of arsenic and manganese above the MCL/PCL were reported in three wells, although manganese concentrations are lower than the background 95%UTL. **Figures 1-17 and 1-18** present the metals concentrations with exceedances above the MCLs/PCLs in the shallow zone and the Wilcox Formation, respectively.
- The source of VOCs in trapped DNAPL is estimated to be present in the shallow zone in the ACD area and southern area of the former UEP, respectively (**Figures 2-1 and 2-2**). The aerial extent of the UEP DNAPL extent is estimated at 35,500 ft^2 and the aerial extent of the ACD DNAPL extent is estimated at 5,000 ft^2. Although the DNAPL investigation in 2014 defined the extent of DNAPL n the vicinity of the ACD (**Figure 2-1**), given the high concentrations of TCE and MC in ICT-12-E (97,400 μg/L and 173,000 μg/L in February 2013, respectively) and monitoring well 120 (24,500 μg/L in May 2013 for TCE), the ACD source area may be extended north from the ACD toward ICT-12E and monitoring well 120, increasing the area to be treated for DNAPL. Under this situation, the cost estimate for the DNAPL area in the vicinity of the ACD may become larger and will be considered during the remedial design phase.
- Unsaturated soil in the area south of the former UEP (in the vicinity of 18SB02 and 8A-911 at a depth of 8 to 12 ft bgs) contains TCE and MC that could leach to groundwater at concentrations exceeding the MCLs. A second area, in the vicinity of 8A-975 at a depth between 5.5 and 12 ft bgs, contains MC that could leach to groundwater at concentrations exceeding the MCL. Data collected in May 2014 adjacent to these boring locations helped

reduce the uncertainty in the lateral extent of TCE and MC. Borings 18CPTUEP09, 18CPTPB16, 18CPTPB17, and 18CPTUEP08 determined the general extent of MC and TCE in the unsaturated zone. A more refined extent determination of CoCs in the soil in these areas is recommended, but will be defined as part of remedial design. The estimated in-place volumes are 414 yd^3 and 602 yd^3, respectively, with both areas having been previously excavated to a depth of 4 ft bgs. **Figure 1-20** depicts the location of soil exceedances.

- Unsaturated soil in the area west of the UEP within the former Burn Burial Area at former sample location 8A-940 at a depth of 4 ft bgs contains TCE and MC that could leach to groundwater at concentrations exceeding the MCLs and at sample location 18CPTBB02 at a depth of 4.5 to 5.5 ft bgs had a perchlorate concentration exceeding the GWP-Ind concentration of 7,200 µg/kg. The extent of perchlorate to the south of 8A-940 has been provided by data collected at 18CPTBB01. Due to the shallow nature of impacted soil, the full extent will be readily determined during the remedial design phase. Several soil samples were collected in the vicinity of 8A-911 from borings 18CPTUEP09, 18CPTPB16, 18CPTPB17, and 18CPTUEP08 in 2015. The data from these borings determine the general extent of MC and TCE in the unsaturated zone, although further refinement of the extent will take place during the remedial design phase. The estimated in-place volume is 416 yd^3. **Figure 1-20** depicts the location of soil exceedances. Two soil areas beneath the UEP had concentrations of TCE and/or MC that exceed the groundwater protection-industrial MSCs. The first area is in the vicinity of 18CPT21 and the second area is in the vicinity of 18CPT25. A conservative extent estimate is 280 ft by 110 ft and a thickness of approximately 10 ft. Thus the estimated in-place soil volume is 11,400 yd^3. Further refinement of the extent will take place during the remedial design phase, particularly since an overlapping area where DNAPL exists may require remediation.

Other than the limited unsaturated soil containing MC and TCE that could leach to groundwater at concentrations exceeding the MCLs, the mass of contaminants can be considered in three parts: 1) mass dissolved in groundwater, 2) mass adsorbed onto soil below the water table, and 3) mass in the form of DNAPL (TCE and MC) or soil contamination (perchlorate). The dissolved and adsorbed mass can be considered accessible mass, readily removed by groundwater extraction, although within the lower K zones, limitations of mass removal will reduce the removal rate of contaminants by groundwater extraction. The DNAPL can be considered source mass and is less readily removed.

Accessible mass of perchlorate was estimated at 8,000 pounds, TCE at 5,700 pounds, MC at 880 pounds, and 1,4-dioxane 3.5 pounds (**Table 2-14**). Source mass (DNAPL) estimates for TCE and MC are 132,000 pounds and 80,000 pounds, respectively (**Table 2-14**). No additional source mass was estimated for perchlorate, since the groundwater concentration was applied to the entire soil column to estimate total mass of perchlorate, which included fine-grained as well as coarse-grained soils. The basis for this assumption is that the highest perchlorate concentration measured in shallow groundwater (118,000 µg/L in 18CPTMW22 in June 2014) does not support the presence of brine in shallow groundwater. No source mass was used for 1,4-dioxane due to its high miscibility in water.

The associated estimates of accessible mass (dissolved and adsorbed) removal times based on 2015/2016 average estimates for groundwater mass extraction rates ranged between 1.2 years for MC to 8.5 years for perchlorate. For secondary source (DNAPL) mass removal, assuming source

mass dissolution is not a limiting factor and mass removal rates remain at the 2015/2016 average levels, the lifecycle duration is estimated at 110 years for MC to 196 years for TCE. There is a significant uncertainty in these estimates of mass and time due to the number and nature of the supporting assumptions. Due to diffusivity and dissolution limitations associated with sorbed mass and DNAPL mass especially in fine-grained soils, the timeframe to achieve the remedial action objectives via groundwater extraction alone is expected to be much longer than estimated above. Nonetheless, the conclusion is that groundwater extraction is not able to restore the site as a sole remedy with time estimates exceeding several hundred years.

Industrial operations, with the potential to contribute contamination, took place across almost the majority of the 34.5-acre LHAAP-18/24 footprint; burning units (trenches, cages, pans) were used for a number of years, including direct placement of chlorinated solvents in trenches with sawdust; the UEP was used for washing out rocket motors, a process using MC to remove materials heavily laden with perchlorate; and, support facilities for storage and other uses existed along the southeastern side of the site. Large amounts of these contaminants, which are highly mobile in many cases, were introduced before these activities ceased. Some of the key contaminants were likely released as free product and travelled along preferential transport pathways through the vadose and saturated zones, pooling in some areas and moving laterally in others. Free product travel would have been independent of the direction of groundwater flow, as it is dictated by the topography of the confining layer.

Source material was removed in the late 1980s and late 1990s. More than 8,000 cubic yards of material was removed at the UEP when it was closed in 1987. The excavation, treatment and off-site disposal of soil during the IRA removed more than 32,000 cubic yards of soil from multiple areas across the site in 1996. Undoubtedly, these activities removed the initial source areas and the most highly-contaminated soil in the vicinity of those source areas. However, final excavation limits were not recorded.

Additionally, throughout the time of operational and IRA cleanup activities, water continued to enter the contaminated region via lateral groundwater flow and vertical infiltration, adding to the groundwater flow and causing further dispersion of the contamination. Thus, any remaining DNAPL will likely be residual, not a clearly defined free phase pool. Along with the historic observation of DNAPL in the groundwater at MW-2, the presence of recent (e.g., May 2013) high CoC concentrations in groundwater at MW-2, and the identification of high soil concentrations from discrete soil samples collected at 18CPT21, 18CPT27, and 18CPTACD03 suggest that two areas at the site should be targeted for secondary source (DNAPL in saturated soil) remediation (See **Figures 2-1** & **2-2** for a depiction of the estimated aerial extent of DNAPL in these two areas).

Finally, the groundwater sampling events between 2014 and 2016 provided a better understanding of the presence and distribution of 1,4-dioxane in Shallow Zone and Wilcox Formation groundwater. Because 1,4-dioxane was identified in groundwater at concentrations exceeding the PCL of 9.1 μg/L, 1,4-dioxane is considered a CoC at the site and a contingent remedy for 1,4-dioxane in groundwater is developed and evaluated in this Revised FS.

4.2 General Response Actions

GRAs are large groups of remedial actions that typically satisfy the RAOs. The GRAs for groundwater, saturated soil secondary source areas (i.e., DNAPL), and unsaturated soil include no action, LUCs, containment, removal, treatment, and disposal. These GRAs may be combined to form remediation alternatives that meet the RAOs. The following are descriptions of the GRAs:

- No Action—The no action GRA is retained throughout the FS process as required by the NCP. The no action alternative provides a comparative baseline against which other alternatives can be evaluated. Under this alternative no remedial action will be taken. The site is considered to be left "as is," with no LUCs, containment, removal, treatment, or other mitigating actions.
- Land Use Control—LUCs includes institutional and administrative controls that would restrict uses of the site. The volume, mobility, and toxicity of the contaminants are not reduced through the application of LUCs. LUCs are generally combined with other GRAs to meet the RAOs.
- Containment—Another method of reducing risk to receptors is through containment, which reduces access to the contaminated medium or the migration potential of the contaminants in the medium. The contaminated medium must be isolated from the primary transport mechanisms such as precipitation migration through the soil column and DNAPL dissolution and groundwater flow to unimpacted areas. This isolation may be accomplished through capping of contaminated soil or the installation of subsurface barriers to prevent groundwater migration.
- Removal—Removal GRAs extract the contaminated medium from its present location and move it to an alternative location for treatment and/or disposal. These removal technologies can be selected to reduce exposure to workers and can be used in conjunction with treatment processes.
- In Situ Treatment—In situ treatment GRAs or process options reduce the toxicity, mobility, or volume of the contaminated medium. Chemicals are added, physical properties of the medium are changed, or biological activity of the medium is modified without removal.
- Ex Situ Treatment—Ex situ treatment GRAs involve the reduction of toxicity, mobility, or volume of contaminated medium. Ex situ treatment processes are typically coupled with removal and disposal process options.
- Disposal—Disposal GRAs involve the discarding of the contaminated medium. Disposal process options are typically coupled with removal and treatment process options.

As noted in earlier sections of this Revised FS, the soil in the saturated zone is expected to contain a considerable amount of contamination adsorbed to soil particles as well as the potential for residual DNAPL. Because the saturated zone soil could serve as a long-term source of contamination for the groundwater, a subset of the GRAs is also applied to that soil. Those GRAs include no action, In Situ Treatment, Ex Situ Treatment, Removal, and Disposal. LUCs and Containment are not screened for the saturated soil, unsaturated soil, and DNAPL because their implementation at LHAAP-18/24 would be fundamentally the same as for the groundwater.

Technologies for saturated soil would not be implemented as stand-alone remedies, but only in conjunction with groundwater remedies.

4.3 Screening of Technologies

This section presents the approach to technology and process option screening. In the technology screening process, GRAs are identified that, by themselves or in combination with other GRAs, could be implemented to meet the RAOs established for LHAAP-18/24. Technologies associated with each GRA and process options associated with each technology are identified. Process options that are not technically feasible for the site are eliminated (screened out) from further consideration. If all of the process options under a given technology are screened out, the entire technology is eliminated.

The technologies and process options are initially screened for technical applicability to identify those to be carried forward for further evaluation. The screening process reduces the number of possible process options for a given technology to a number that is appropriate for consideration at LHAAP-18/24. The following are the two general criteria used to determine if a technology or process option should be retained for further evaluation:

- Applicability to the type and combination of contaminants
- Applicability to the site's physical conditions

Table 4-1 presents the technologies and process options considered for LHAAP-18/24 groundwater, unsaturated soil, and saturated (secondary source) zone soil (areas with residual DNAPL). Process options not considered technically applicable were not retained for further evaluation; the rationale for their elimination is shown in the table.

4.4 Evaluation and Selection of Representative Process Options

In this section, each of the process options retained from the initial screening in **Section 4.3** (**Table 4-1**) are further evaluated and screened, further reducing the list of process options that are developed into alternatives in **Section 5.0**. Process options are evaluated using three criteria: effectiveness, implementability, and cost. Based on these criteria, representative process options are selected for each technology. The representative process options provide a basis for developing alternatives in the FS.

The general descriptions of the process options retained from the screening, along with the relevant aspects of effectiveness, implementability, and cost, are discussed. The effectiveness evaluation considers the following: (1) the potential effectiveness of process options in handling the estimated areas or volumes of the contaminated medium; (2) the contribution toward meeting any of the goals identified in the RAOs; (3) the potential impacts to humans and the environment during the construction and implementation phase; and (4) how proven and reliable the process is with respect to the contaminants and conditions at the site.

The implementability evaluation considers both the technical and administrative feasibility of implementing a process option. Implementability concentrates on the difficulty of implementing the option, including the number of treatability studies required, the extent of innovative design required, and the extent of site preparation needed. Unusual equipment or unusual conditions for standard equipment may decrease the ease of implementation. The institutional aspects of

implementability such as meeting the substantive requirements of permitting and availability of services are also considered.

The cost evaluation focuses on the relative capital and operation and maintenance (O&M) costs required. A ranking of high, medium, or low relative to other similar process options is given, each ranking considering both capital and O&M costs. Based on this evaluation, one or more representative process options are selected for each response action to be carried forward into the development of alternatives. The selection of representative process options for the development of alternatives does not eliminate the remaining process options from future consideration. Those process options not carried forward may be reconsidered during the development of the PP, ROD, or remedial design.

4.4.1 Groundwater

In the following subsections, process options are evaluated to address groundwater contaminated with VOCs, metals, and perchlorate. Process options specific to 1,4-dioxane will be included as a contingency. The evaluation is presented graphically in **Figure 4-1**.

4.4.1.1 No Action

The "no action" process option provides no groundwater remedial activities. No monitoring of the groundwater or surface water conditions occurs under this process option. This process option is retained as a baseline with which other remediation alternatives are compared.

- **Effectiveness –** Without access controls or remediation, the groundwater from LHAAP-18/24 could result in a future unacceptable risk to humans if the groundwater is ingested or the groundwater could migrate to surface water. RAOs cannot be achieved with this option.
- **Implementability –** No implementation is required.
- **Cost –** None.

4.4.1.2 Land Use Control

This LUC process option would be implemented to achieve the following at LHAAP-18/24.

- A LUC prohibiting potable use of groundwater above cleanup levels until it is demonstrated that the COCs in soil and groundwater are at levels that allow for unlimited use and unrestricted exposure.
- A LUC restricting land use to non-residential until it is demonstrated that the COCs in groundwater and surface and subsurface soil are at levels that allow for unlimited use and unrestricted exposure.
- A LUC requiring protection and maintenance of the existing UEP cap.
- A LUC to maintain the integrity of any current or future remedial or monitoring systems will remain in place until groundwater cleanup levels of COCs are met.

- A LUC restricting the use of groundwater to environmental monitoring and testing only will remain in place until the levels of COCs in surface and subsurface soil and groundwater allow for unlimited use and unrestricted exposure.

The U.S. Army will perform notification of these land use controls which will accompany all transfer documents and will be recorded in the Harrison County Courthouse. Periodic monitoring will be performed to document that the land use controls remain in effect. LUCs do not achieve RAOs (e.g., preventing groundwater migration to surface water) but can be used in conjunction with other process options to achieve RAOs.

4.4.1.2.1 Access Restrictions

Use controls would be implemented to restrict access to the groundwater. The process options for access restrictions include legal restrictions, administrative controls, and physical mechanisms.

Legal Restrictions. Restrictions to the groundwater can be accomplished through modifications to the property deed or agreements about land use. Legal restrictions can be placed on the installation of groundwater extraction wells not only to prevent access to the contamination, but also to minimize the possibility of moving the contamination toward a future user. A recordation of the LUCs (including restriction to groundwater use) will accompany the transfer documentation from the U.S. Army to the USFWS. Deed restrictions would be needed only if the U.S. Army releases the property to a non-federal entity. These restrictions are effective only as long as the property owners and local authorities enforce them. The U.S. Army is ultimately responsible for the enforcement of the LUCs.

- **Effectiveness –** Because the future use of the site is by a federal agency as a refuge, LUCs are highly effective. These actions can limit or prevent exposure to contaminants remaining on the site after remediation and can be implemented on a temporary basis. Periodic maintenance and Five-Year Reviews will ensure that the restrictions are enforced and remain effective.
- **Implementability –** These options can be readily implemented and are easily implemented by the USFWS since the refuge use is compatible with the main refuge activities per the Wildlife Refuge Act provisions, which are all nonintrusive and limited impact activities. The Refuge System manages six wildlife-dependent recreational uses in accordance with the National Wildlife Refuge System Improvement Act of 1997, including hunting, fishing, birding, photography, environmental education, and interpretation.
- **Cost –** Low.

Administrative Controls. Administrative controls consist of the use of training or procedures to limit access to the site and reduce the risk to human health posed by site contamination. These measures may include internal notices and site inspections to serve as a reminder of the existence of LUCs, a site approval process to review land-use changes at LHAAP-18/24 to ensure the LUCs are followed, training of site personnel regarding the existence and care of the LUCs, and regular inspection and maintenance of the LUCs. These are controls the U.S. Army can use while it maintains control of the site.

- **Effectiveness –** Administrative controls are effective in controlling human intrusion into contaminated areas during and after remediation. The training required for access to the site limits potential exposure to the contaminated groundwater. Administrative controls can be used in conjunction with physical mechanisms. This option is effective due to the use of the site as a wildlife refuge.
- **Implementability –** Training and procedures are readily available and implemented. They may need to be modified for LHAAP-18/24.
- **Cost –** Low.

Physical Mechanisms. It is anticipated that administrative controls will be adequate to control access to the contaminated groundwater and soil and that physical mechanisms will not be required.

4.4.1.2.2 Monitoring

Monitoring and surveillance are used to assess the performance of remedial actions and verify compliance with the established RAOs. Process options for monitoring are physical surveillance and long-term media monitoring.

Physical Surveillance. Visual and physical inspections of engineered remedial action components can detect physical changes (e.g., iron deposition and pipeline cracks) that may ultimately lead to the failure or unsatisfactory performance of that component. Repairs and/or revised maintenance activities can be implemented as a result of these inspections.

- **Effectiveness –** Physical surveillance is effective in determining the continued integrity of engineered systems and the need for repairs and/or replacement. Physical surveillance needs to be used with contaminant monitoring to assess the impact of integrity failure.
- **Implementability –** Physical surveillance is easily implemented and requires experienced, but readily available personnel to make regular visits to the site for inspections.
- **Cost –** Low.

Long-Term Media Monitoring. Environmental media (e.g., groundwater) can be monitored during and after the implementation of the remedial action to determine the effect the remedy has had on the level of contamination. Long-term media monitoring can detect a potential failure of the action to meet the RAOs. Monitoring can also be used to detect changes in expected site conditions or changes in the expected effectiveness of the remedy, and indicate whether additional actions should be implemented or whether ongoing actions can be terminated.

- **Effectiveness**—Long-term media monitoring would be successful in evaluating the effectiveness of a remedial alternative. The effectiveness of the monitoring system depends on the design of the monitoring plan.
- **Implementability**—Equipment and personnel are readily available. The site is readily accessible, and most monitoring techniques have already been implemented at LHAAP. Multiple groundwater-monitoring wells are already in place, and there is a reasonable baseline of groundwater conditions.

- **Cost**—Moderate due to labor and analytical costs but can become substantial over longer periods of time.

4.4.1.2.3 Summary of Land Use Control Process Options

Administrative controls, physical surveillance, and long-term media monitoring are carried forward as representative process options for the LUCs GRA. Notification of industrial/recreational use will accompany all transfer documents and will be recorded in the Harrison County Courthouse. The covenants would only be used if the U.S. Army releases the land to a non-federal entity. All of these process options could be combined with other process options to meet the RAOs.

4.4.1.3 Containment

Containment consists of technologies that contain groundwater in place to prevent further migration or immobilize it for in situ treatment. The containment technologies considered are hydraulic containment and physical containment. The process options for hydraulic containment are identical to those for groundwater removal, and are discussed in the following **Section 4.4.1.4**. Physical containment process options fall into two categories:

- **Lateral containment –** slurry walls, grout curtains, and sheet pilings.
- **Capping –** soil covers, asphalt caps, multilayer caps.

Capping technology is intended to be applied in conjunction with a lateral containment option to minimize infiltration of surface water/precipitation and stabilize the water table (i.e., reduce the outward migration of groundwater from the site). Portions of LHAAP-18/24 may require some initial clearing, particularly outside the containment area.

4.4.1.3.1 Lateral Containment

Slurry Wall. A slurry wall is a continuous low permeability subsurface trench formed by mixing clay minerals (typically bentonite) with in situ soil to contain contaminated groundwater. It is constructed very much like an ICT with the exception that the intent is to prevent groundwater movement rather than encourage it. The slurry wall can be installed around the entire area of a shallow plume to effectively contain contaminated groundwater from lateral migration.

- **Effectiveness –** Slurry walls are very effective at containing groundwater horizontally. The trench functions like a continuous wall preventing the passage of groundwater. Slurry walls are only applicable to shallow zone contamination.
- **Implementability –** Slurry walls are relatively easy to install with the appropriate construction equipment, deep trencher, long-stick excavator, deep soil mixer. The process requires little long-term maintenance. Slurry walls become more difficult to install with greater depths as equipment becomes more specialized and costs per linear foot rise.
- **Cost –** Moderate.

Grout Curtain. A grout curtain is a low permeability subsurface barrier formed by injecting chemicals such as sodium silicate or cement-based grout in a series of overlapping columns to

form a barrier to groundwater flow. The grout curtain can be installed around the entire area of a shallow plume to effectively contain contaminated groundwater.

- **Effectiveness –** Grout curtains are effective at containing groundwater horizontally. The grout curtain prevents the passage of groundwater if well-constructed of materials compatible with the groundwater and contaminants. Grout curtains are only applicable to shallow zone contamination. Soil heterogeneity which is present at the site may result in an uneven distribution of grout that could result in leaks. Injected chemicals may interfere with NA processes at the site.
- **Implementability –** Grout curtains are relatively easy to install with the appropriate high pressure soil grout injection equipment. The process requires little long-term maintenance. Grout curtains may leak at improperly overlapped columns, with injection failure, or if chemical degradation occurs over time.
- **Cost –** Moderate.

Sheet Piling. Sheet piling can form an impermeable subsurface barrier by driving impermeable sheets of steel or synthetic material into the ground to form a barrier to groundwater flow. The sheet piling can be installed around the entire area of a shallow plume to effectively contain contaminated groundwater.

- **Effectiveness –** Sheet piling can be effective at containing groundwater horizontally. The sheet piling prevents the passage of groundwater if well-constructed of materials compatible with the groundwater and contaminants. Sheet piling is only applicable to shallow zone contamination. Sheet piling may leak at joints, or through holes in the sheet piles if chemical degradation occurs over time.
- **Implementability –** Sheet piling is relatively easy to install with the appropriate pile driving equipment, or they can be laid into an excavated trench that is later backfilled. Sheet piling requires little long-term maintenance.
- **Cost –** Moderate. However, there are uncertainties regarding long-term steel prices.

4.4.1.3.2 Summary of Lateral Containment Process Options

Slurry wall is retained as a representative groundwater containment process option because of their extensive use in environmental restoration actions. Grout curtain is not retained as a process option because applied grout could interfere with active NA. Sheet piling is not retained as a process option because it offers no significant containment advantage over a slurry wall.

4.4.1.3.3 Capping

Soil Cover. Soil covers consist of a layer of fine-grained soil placed and compacted over contamination and covered with a top soil layer. Vegetation is generally encouraged to limit erosion.

- **Effectiveness –** While not as effective as asphalt caps or multilayer caps, a properly designed soil cover can be effective at promoting runoff and reducing infiltration. A simple Hydrologic Evaluation of Landfill Performance (HELP) model of a soil cap indicated infiltration would be reduced by 83 percent.

- **Implementability –** Soil covers are easy to implement. Standard earthmoving equipment can move local soil over the contaminated areas. Portions of LHAAP-18/24 may require some initial clearing, particularly outside containment area. Soil cover maintenance to limit large vegetative growth that could disrupt the cover and to control erosion would be needed. Frequent maintenance (mowing) would be required.
- **Cost –** Low to moderate depending on the area of coverage.

Asphalt Cap. Asphalt caps control infiltration of rainwater or run-on water through the installation of impermeable asphalt. This process option is particularly useful if the site is to be used as a parking lot or other light industrial use.

- **Effectiveness –** Asphalt caps can be effective at reducing infiltration if sufficient maintenance occurs. Asphalt can quickly develop cracks and holes that need to be filled, and maintenance will be needed to repair them as they occur. These caps are most effective if the area needs to be asphalted for another use that will promote its long-term maintenance.
- **Implementability –** Asphalt caps are easy to install but require the land to be leveled and compacted below the asphalt and an asphalt base added. As with other caps to control infiltration, they need to be sloped to encourage runoff during rain events. Frequent maintenance is less necessary than with multilayer caps as the asphalt does not require mowing. However, the asphalt cracks easily and this must be controlled to maintain effectiveness.
- **Cost –** Low to moderate depending on the area of coverage.

Multilayer Cap. A multilayer cap is an engineered cover that can consist of various layers of soil, clay, membranes and other materials. Multilayer caps control infiltration of rainwater or run-on water through the installation of impermeable layer materials.

- **Effectiveness –** Multilayer caps can be effective at reducing infiltration if sufficient maintenance occurs. Long-term maintenance would be required to ensure cracks and holes do not develop. Maintenance will be needed to repair cracks as they occur. A simple HELP model of synthetic liner reduced infiltration by 99 percent.
- **Implementability –** A multilayer cap is more difficult to implement than a soil or asphalt cap due to the design and installation requirements. As with other caps to control infiltration, they need to be sloped to encourage runoff during rain events. More maintenance is necessary with multilayer cap than the asphalt cap as frequent mowing is required. The multilayer cap must be inspected and maintained to ensure its long-term effectiveness.
- **Cost –** High.

4.4.1.3.4 Summary of Capping Process Options

The UEP area at LHAAP-18/24 is already capped. Capping options can readily be implemented on other portions of the site and could include drainage improvements (e.g., lined ditches) that would promote better runoff and reduce infiltration. When used in conjunction with lateral containment, a cap would help control the water table within the contained area and could prevent an outward gradient that would otherwise drive migration of contaminated groundwater. If a cap is used, minimizing or eliminating infiltration of rainwater, in conjunction with the

existing impermeable barriers along the northwest and southwest boundaries of the site, flow through the site could be extremely restricted. Extreme restriction of groundwater flow through the site could result in marginalization of groundwater extraction and contaminant recovery. That said, the capping process option will be retained to allow better flexibility in developing remedial alternatives.

All three capping options would be acceptable, but the soil and asphalt caps are much lower cost options. Without a definitive reason to pave the area, the soil cover will be used as the representative process option. As indicated above, the use of a cap with a slightly lower performance (i.e., a soil cap versus a multilayer cap) is preferred to reduce infiltration to groundwater in the area of high water table, but not to marginalize on-going groundwater recovery via the extraction system.

4.4.1.4 Removal

The removal GRA consists of technologies that remove groundwater to either relocate it or prepare it for treatment. The removal technology considered is groundwater collection/removal. Groundwater collection and removal is accomplished by either vertical extraction wells, interception trenches, or horizontal extraction wells.

4.4.1.4.1 Vertical Extraction Wells

These are vertically installed wells designed to collect and extract clean or contaminated groundwater to contain a plume or to reduce contaminant mass in the plume.

- **Effectiveness –** Extraction wells are considered the most effective groundwater removal technology applicable over a wide range of site conditions. However, proper locations need to be selected to provide for effective extraction and long-term operation. To maintain operability, frequent maintenance to the pumping system is required due to high potential for iron fouling at this site.
- **Implementability –** This process is the single most commonly used method to remove groundwater in a very wide range of conditions. New wells will be installed in areas with high contamination or areas that would intercept groundwater before it reaches a potential receptor, such as surface water. Extraction wells are easy to install at all depths that might be required at LHAAP-18/24, including shallow zone and Wilcox Formation wells. Existing monitoring wells at LHAAP-18/24 could be converted to extraction wells.
- **Cost –** Low to moderate dependent on number and depths of wells required.

4.4.1.4.2 Interception Trenches

An interception trench is a high permeability subsurface trench that collects contaminated groundwater. It is constructed and operates similar to a vertical French drain, with the exception that collected groundwater is actively pumped from the trench for ex-situ treatment. The trench can be installed across the entire width of a shallow plume to more effectively capture contaminated groundwater.

- **Effectiveness –** Interception trenches are very effective at collecting groundwater. The trench functions like a continuous line of extraction wells. The trenches are only applicable

to shallow zone contamination. Their advantage in a heterogeneous environment is the ability to intercept various conductive zones that may not be interconnected. To maintain operability, frequent maintenance to the pumping system is required due to high potential for iron fouling at this site.

- **Implementability –** Interception trenches are relatively easy to install with conventional construction equipment. The process requires long-term maintenance to ensure that the permeable media and collection piping do not become clogged, particularly in a high iron groundwater environment. Interception trenches would be difficult to install in the Wilcox Formation (i.e., at depths greater than 45 ft bgs).
- **Cost –** Moderate to high depending on number, depth, and total length of trenches.

4.4.1.4.3 Horizontal Wells

Horizontal wells are similar to vertical wells with the exception that they are installed horizontally and are typically screened throughout their entire length. They function like drains and offer a water removal capability that exceeds that of a similarly sized vertical well, although testing conducted in the 1990s revealed that vertical wells are more effective than horizontal wells at this site. Horizontal wells could be installed under source areas to remove contaminated groundwater or collect migrating leachate.

- **Effectiveness –** Horizontal wells are very effective at removing large volumes of contaminated groundwater in applications where vertical wells cannot be used. Wells up to 12 inches in diameter and 10–500 ft deep can be installed over 1,000-foot lengths. Field tests in the 1990s revealed that horizontal wells at LHAAP-18/24 are not as effective, although advancements in directional drilling technology since the 1990's occurred.
- **Implementability –** Although this process is commonly used in the oil industry, it is still in the demonstration phase in environmental restoration. It would likely be used underneath a source area to collect contaminated groundwater or leachate.
- **Cost –** High.

4.4.1.4.4 Summary of Removal Process Options

Horizontal wells are not retained as a representative groundwater removal process option because of their limited use in environmental restoration actions, their high costs, and the limited effectiveness at LHAAP-18/24 as determined in 1990s field experiments, when compared to interception trenches. Vertical extraction wells and interception trenches are currently in use at LHAAP-18/24 with the existing groundwater extraction system. Thus, vertical extraction wells and interception trenches are retained as process options for alternative development. Although not retained as a process option for remedial action, horizontal wells could be used as an alternative to ICTs should the need arise to replace existing ICTs.

4.4.1.5 In Situ Treatment

In situ treatment technologies provide varying levels of groundwater treatment without prior removal of the groundwater, and reduce the mobility and/or toxicity of the contaminants in

groundwater. The in situ treatment technologies under consideration are physical/chemical and biological treatments.

4.4.1.5.1 Physical/Chemical Treatment

MNA, air sparging/soil vapor extraction, in situ oxidation, permeable reactive barriers, thermal treatment, electrokinetics, and nanotechnology are process options considered potentially applicable to the groundwater at LHAAP-18/24.

Monitored Natural Attenuation. MNA is a remedial process option that will achieve the cleanup levels over time. Natural subsurface processes such as dilution, volatilization, biodegradation, adsorption, and chemical (abiotic) reactions with subsurface materials are monitored to confirm their progress in reducing contaminant concentrations. **Appendix A** provides an evaluation of the ongoing NA at LHAAP-18/24. The VOCs and perchlorate are amenable to MNA. While 1,4-dioxane is amenable to MNA, it was not evaluated due to limited amount of data available for 1,4-dioxane.

In situ microcosm (ISM) study was deployed in monitoring wells MW2 and 120 for 84 days using Bio-Traps obtained from Microbial Insights. The study included monitoring for natural attenuation using a control unit, as well as biostimulation units amended with either oxygen releasing compound (ORC) or emulsified vegetable oil (EVO) to study aerobic and anaerobic enhancements, respectively. ^{13}C labeled MC was embedded in the Bio-traps. The results indicated no evidence of natural attenuation is taking place in MW2 for MC but some evidence of NA occurred in monitoring well 120. ORC enhanced degradation of MC in monitoring well 120 but EVO did not. EVO did not enhance biodegradation in MW2 while ORC indicated some stimulation but very limited. These results indicate that high concentration areas are not amenable to natural or enhanced biodegradation while natural or enhanced biodegradation was observed in low concentration areas.

- **Effectiveness –** MNA is considered under CERCLA on a case-by-case basis. USEPA guidance has been developed to aid in the selection of this process option for VOCs. MNA has been selected for a number of CERCLA sites. MNA is effective when source releases have been mitigated, off-site releases of contaminants at unacceptable levels are not occurring, and it can be demonstrated that NA mechanisms are occurring. Regular monitoring must be conducted throughout the process to confirm that attenuation is occurring in accordance with cleanup objectives. The MNA evaluation for LHAAP-18/24 (see **Appendix A**) demonstrated that NA is occurring at LHAAP-18/24, but not with high certainty or adequate consistency. Additionally, the rates of MNA are slow such that short-term effectiveness is uncertain for VOCs and perchlorate. MNA is also effective for metals due to sorption and precipitation processes. MNA would be primarily applicable to dilute dissolved phase plumes.
- **Implementability –** Significant groundwater sampling and analyses must be performed to confirm that conditions are suitable for NA and to establish a monitoring network. It must also be confirmed that additional source releases and unacceptable off-site releases are not occurring.

- **Cost –** Low to moderate but could be high with specialty tests, large number of monitored locations, and if MNA takes an extended timeframe to achieve the RAOs as would be expected for this site.

Air Sparging/Soil Vapor Extraction. This process option is designed to remove VOCs from the groundwater by volatilizing these contaminants through the introduction of air. Air is introduced into the groundwater, assisting in the volatilization of those organics in solution in the groundwater. Extraction wells are installed into the vadose zone and a vacuum is drawn on these wells. The extraction system draws off the organic-laden air that was bubbled through the groundwater in addition to any vapors that exist in the soil pore spaces. The volatilized contaminants can then be drawn from these extraction wells and treated. This process can be used in those areas where VOCs exist in the groundwater and the vadose zone above this groundwater is relatively permeable.

- **Effectiveness –** This process is very effective on highly volatile contaminants (e.g., TCE) and highly permeable formations. It is incompatible with certain soil types, and high humic content inhibits volatilization of contaminants. Implementation at LHAAP-18/24 is complicated by the subsurface heterogeneity and high clay content soil that may limit the effectiveness of air sparging by retarding the movement of air and vapors through the soil column. The presence of discontinuous high-permeability zones can result in preferential air flow paths, limiting the effectiveness. Air sparging is not effective for remediating perchlorate or metals and less effective for remediating 1,4-dioxane compared to VOCs.

- **Implementability –** Vapor extraction and air sparge equipment is readily available and commercial vendors are available to design and operate these systems. This process has been used at many hazardous waste sites in relatively homogeneous media. Organics that are removed from the vapor extraction wells require ex situ treatment. Site characterization and modeling are required to determine the proper location of the injection and extraction wells and extraction rates.

- **Cost –** Low to moderate.

In Situ Oxidation. Contaminated media are treated through the addition of oxidizers, such as potassium permanganate, hydrogen peroxide, or activated persulfate, which convert the contaminants to a less mobile or toxic form. This process option is applicable to VOCs such as TCE and 1,4-dioxane.

- **Effectiveness –** In situ oxidation is effective on contaminants in a relatively homogeneous and porous medium. The shallow groundwater zone at LHAAP-18/24 is largely non-homogenous, of variable porosity, and discontinuous from well to well. Chemical oxidation is most effective for VOCs (particularly TCE) and is considered a suitable approach for the primary CoCs at LHAAP-18/24 (MC and TCE). Some chemical oxidants are effective on 1,4-dioxane such as Fenton's reagent and activated persulfate, but others are not effective such as permanganate. Chemical oxidation is not effective for treatment of metals, perchlorate, or chlorinated alkanes such as 1,2- dichloroethane (DCA).

- **Implementability –** This process option is readily implementable but concerns regarding distribution and exposure of the contaminants to the chemical agents exists. An additional concern is the release of excess reactants or byproducts to the environment. In-situ

applications of these processes are well established. A recent USEPA evaluation by their Technology Innovation Office concluded that the application of in situ oxidation is highly dependent on the delivery system.

- **Cost –** Low to moderate.

Permeable Reactive Barriers (PRBs). Permeable reactive barriers can be a physical/chemical or biological treatment option. A reactive barrier or gate is a permeable wall containing reactive media that is constructed across the path of a contaminant plume. As contaminated water passes through the wall, the contaminants are removed or degraded, allowing uncontaminated water to emerge on the downgradient side. Reactive barriers are usually installed through adaptation of conventional construction methods for impermeable barriers such as open trenches, polymer slurry trenches, and overlapping caissons. Reactive barriers may be constructed from a variety of materials including zero-valence metals (ZVM), granulated activated carbon (GAC), biological organic material, and other sorbents. These materials treat contaminants through a combination of mechanisms, including adsorption, chemical reduction, and biodegradation.

ZVM works by chemically reducing contaminants, thus either causing their degradation or limiting their mobility. A variety of metals can be used as reducing agents such as silver, gold, palladium, copper, zinc, aluminum, manganese, and iron. In situ reactive gates require high volumes of ZVM, making the application of precious metals such as silver, gold, and palladium impractical. The most practical metal for this technology is iron, because of its relative abundance, low cost, and low toxicity. However, more expensive yet more effective forms of iron (palletized iron) may be necessary, depending on contaminant concentration. ZVM is not effective in treating perchlorate or 1,4-dioxane.

GAC is the most widely used adsorbent and filter medium because of its effectiveness on a variety of contaminants. GAC is chemically stable and will not produce secondary contaminants. The surface area of the carbon and the pH of the solution flowing through the medium determine the rate and effectiveness of GAC in adsorbing contaminants. In addition, different contaminants are adsorbed according to different ionic natures and kinetics.

- **Effectiveness –** The effectiveness of this process depends greatly on the contaminants, the reactive media, site hydrology, and site geochemistry. Reactive media clogging and exhaustion causes the need for periodic replacement. The gates are generally limited to shallower applications because of the difficulties in installing and monitoring the media at depth. There are concerns over the longevity of the reactive media given uncertain and changing chemical and physical conditions and the potential high load of CoCs through the gate that could exhaust the reactive barrier material rapidly. PRBs are limited by the CoC migration rates through the formation, particularly through fine-grained soils. GAC effectiveness is reduced once its capacity diminishes over time. GAC is not effective for perchlorate, 1,4-dioxane, or metals.
- **Implementability –** Permeable reactive barriers require adequate site and contaminant characterization and monitoring to determine effectiveness. This process requires treatability testing before full-scale implementation to determine potential physical and chemical interactions with surrounding materials, location within the aquifer, and criteria for replacement.

- **Cost –** moderate to expensive depending on length and depth of reactive barriers and material used.

Thermal Treatment. Heating the subsurface can effectively and quickly volatilize large quantities of VOCs, including those in the form of nonaqueous phase liquid. Available technologies include electrical resistance heating (ERH), steam injection, and conductive heating which are typically coupled with a soil vapor extraction system to capture VOCs. ERH delivers electricity to the subsurface through an array of electrodes. The heat generated by electrical resistance typically can raise subsurface temperatures to around the boiling point of groundwater. The steam produced from the groundwater serves as a medium to carry out volatilized VOCs. Steam injection involves the ex situ generation of heat and steam, which is delivered to the subsurface through new or existing wells. Similar to ERH, VOCs are volatilized and carried to the soil vapor extraction system by steam. Conductive heating involves applying heat and vacuum simultaneously to subsurface soils with an array of vertical heater/vacuum wells. Heat generated from heating elements is transferred to the subsurface largely via thermal conduction and radiant heating. In addition, heat can promote in situ biological activity in two ways. First, biological activity is boosted by moderately high temperatures (30 C) found at the periphery of the heated area during active thermal treatment, and throughout the heated area as it cools. Second, high temperatures increase the solubility of DNAPL (if it is present), resulting in increase in contaminant concentrations in the dissolved form that the microbes are able to use.

- **Effectiveness –** Removal of TCE, MC, and other VOCs, as well as 1,4-dioxane, is anticipated to be effective in high concentration areas, including where DNAPL may exist. Thermal treatment does not suffer from the same limitations of subsurface heterogeneity like the other in-situ technologies and should be effective in treating coarse-grained material and low K zones alike. High flow zones have been problematic because they transport the heat away from the targeted area more quickly than low K zones. However, temperature distribution in the subsurface can be made more uniform based on the duration of application of thermal treatment. Additionally, the majority of contamination resides within fine-grained units. VOC concentrations in thermally-treated groundwater may reach an asymptote; therefore, a follow-up treatment method is likely to be necessary to reach RAOs, including MNA. Thermal technology is not anticipated to have an effect on perchlorate (an ion) or metals.

- **Implementability –** Additional site characterization to better define DNAPL (especially with ERH because of the cost of installing electrodes) has been conducted and site samples were collected and tested for total organic carbon and thermal resistivity by the technology vendor. The results (**Appendix C**) indicated that the site is amenable to thermal treatment. A significant disadvantage to thermal treatment is that it may compromise the high-density polyethylene (HDPE) liners installed along the northern and western perimeters of the site, as well as the network of HDPE piping in the shallow soil (which carries groundwater to the treatment plant). However, the location where DNAPL is present is relatively far from ICTs with HDPE liners and direct impact is not anticipated. Additionally, affected HDPE components could be replaced following thermal treatment, but replacement costs would be significant for the liner. Should the need arise to protect HDPE liners, the treatment could be operated at lower temperatures or operated away from the liner; both would lower overall effectiveness of the technology if certain target areas are not treated.

- **Cost –** High to very high.

Electrokinetics. Electrokinetics techniques use low voltage direct current (DC) in the order of milliamps per centimeter square (mA/cm^2) of cross-sectional area between the electrodes or an electric potential difference on the order of a few volts per cm across electrodes placed in the ground in an open flow arrangement (GWRTAC, July 1997). Typically groundwater is used as the conductive medium. The open arrangement of electrodes allows placement or removal of processing fluids or of the pore water into and out of the porous medium. Water, ionic species, nonionic species, and particles can be made to migrate under induced potential via electroosmosis, electromigration, and electrophoresis (GWRTAC, July 1997). Electroosmosis is the movement of soil moisture or groundwater from the anode to the cathode of the electrolytic cell, which carries with it dissolved nonionic species. Electromigration is the transport of ions and ion complexes to the electrode of opposite charge. Electrophoresis is the transport of charged particles or colloids under the influence of an electric field, carrying bound contaminants with them.

The electrodes are inserted in the ground within the contaminated zone and a DC is applied. The electrodes are typically 3 to 10 feet apart inserted to the depth of contamination. The migration rate of dissolved constituents in soil pore water is typically one (1) inch per day, requiring a treatment time of 36 to 120 days (GWRTAC, July 1997). For large sites, this process will take a very long time to achieve remedial objectives and multiple simultaneous applications would be required. The advantages of electrokinetics are its effectiveness in fine-grained soils and for in situ treatment of heavy metals. Technology limitations include solubility of contaminants to be treated, corrosion of anode material, migration rates are slow, change in ambient pH could lead to precipitation and fouling of the cathode, and the presence of large quantities of iron or iron oxides can reduce removal efficiencies.

A variation of electrokinetics is the Lasagne™ process, which was developed in cooperation between the USEPA and a private consortium was demonstrated to treat TCE DNAPL in tight clay soil with removal efficiencies of 98% in soil up to 15 feet bgs (GWRTAC, 1997). The process can be described based on layering of the electrodes and treatment zones for sorption, immobilization, and/or degradation of contaminants (Gomes et. al., 2012). TCE was mobilized into carbon-containing treatment zones where it was trapped. The process involves creating in situ reactive zones to treat CoCs in situ without extraction. The Lasagne™ process could overcome many of known limitations of electrokinetics and avoids above ground remediation needs.

Enhanced electrokinetics is used to reduce some of the limitations of this process and include:

- Electrokinetic bioremediation: where nutrients and bacteria could be introduced and allowed to migrate through the contaminated zone via induced current to enhance in situ bioremediation (ISB).
- Electrokinetic oxidation: where oxidants, such as Fenton reagent or permanganate, are introduced at the electrodes to oxidize transported contaminants.
- Electrokinetic with permeable reactive barrier: the current is induced across the barrier allowing contaminants to pass through the barrier where decontamination could take

place. Reactive barriers typically contain zero valent iron, activated carbon, and other material.

- Electrokinetic with surfactants: use of surfactants to enhance desorption of contaminants facilitates migration under induced current for improved removal of contaminants.

Extraction of fluids mobilized to the electrodes for above ground treatment would be required which increases the complexity and cost of the process.

- **Effectiveness –** Removal of TCE, MC, and other VOCs is anticipated to be effective in high concentration and fine grained soil areas, including where DNAPL may exist. Some volatilization of VOCs could occur. Effectiveness depends on a lot of factors such as grain size, ionic strength (cation exchange capacity and salinity), contaminant concentrations, soil type and structure, and presence of high concentrations of other naturally occurring material such as iron. On its own, electrokinetics has severe limitations such as precipitation (fouling of) on electrodes, severe pH increase in soil, and solubility limitations of contaminants. The site has a very high iron content and with increasing pH, fouling due to precipitation or iron could compromise the success of the process. Therefore, electrokinetics combined with other technologies (enhanced electrokinetics) would be required to minimize limitations and improve opportunity to mobilize contaminants for removal or in situ treatment (e.g., oxidation and bioremediation).
- **Implementability –** Prior to implementing full scale treatment, it may be appropriate to perform additional soil characterization to better define potential limiting factors. Studies include field electrical conductivity surveys, pH and electrical conductivity of pore water, major dissolved ion concentrations in groundwater/pore water, buffering capacity and geochemistry of soil (cation exchange capacity (CEC) and salinity). Treatability testing to ensure that the system design delivers as expected might be required. Areas where ICTs are present may not be candidates for remediation as these ICTs will interfere with contaminant migration and continuity of induced currents. Although these ICTs could be used to extract mobilized contaminants for treatment. However, this approach requires a focused study to understand the dynamics and limitations.
- **Cost –** High to very high.

Nanotechnology. Remediation of groundwater and DNAPL using nanoparticles containing zero valent iron (nZVI) is a promising technology, which has been implemented on several sites for treatment of chlorinated VOCs (EPA, December 2007). A nanoparticle is defined by the American Society for Testing and Materials (ASTM) as an object with at least one dimension in the 1 to 100 nanometer (nm) range (EPA, October 2008). Nanoparticles have greater reactivity than larger sized particles in the millimeter range due to their larger overall specific surface area but not due to greater density of reactive sites on the particle surfaces or higher intrinsic reactivity of the reactive surface sites as sometimes speculated (Tratnyek and Johnson, May 2006). This characteristic results in a more rapid degradation of contaminants that already react at useful rates with larger particles. However, this high reactivity correlates with low selectivity, which makes remediation with nZVI susceptible to inefficiency because of the reaction of particles with nontarget substances, including dissolved oxygen and water. This 'natural demand' implies that nZVI will have a limited lifetime in environmental media, necessitating reinjections of nZVI and thereby adding to the cost of treatment (Tratnyek and Johnson, May

2006). Treatment of perchlorate by nZVI is indirect and occurs by enhancing the geochemistry of the environment where nZVI is introduced to biodegrade perchlorate by indigenous bacterial populations (Xueyuan et. al., 2006). Treatment of metals such as arsenate, selenite, and hexavalent chromium occurs in the presence of nZVI. nZVI is not effective in treating 1,4-dioxane.

Due to manufacturing limitations, many nZVI contain larger-sized particles (i.e., > 100 nm), additionally due to aggregation of nanoparticles in the subsurface that result in generation of larger particles, transport of nZVI in groundwater is limited from a few inches to a few feet (Tratnyek and Johnson, May 2006) and incorporation and distribution of injected ZVI into low K zones will not be as effective to treat this medium that contains a large mass of residual DNAPL. Therefore, other forms of nZVI were manufactured such as emulsified ZVI (EZVI). This product consists of ZVI surrounded by an oil-liquid membrane, made from food grade surfactants, biodegradable oil, water, and nanoscale iron in an emulsion form. The exterior oil membranes of the droplets are hydrophobic, as are DNAPL contaminants such as TCE. The droplets are therefore miscible with the DNAPL, allowing increased contact between the TCE DNAPL and the ZVI within the droplets via dissolution and diffusion into the droplet (EPA, October 2008). EZVI appears to be more effective in treatment of TCE than nZVI. The vegetable oil also enhances biological activity and destruction of the contaminant.

Other forms of nanoparticles are combining other metals with iron such as palladium or gold to generate bimetallic nanoparticles (BNPs). The combination of metals increases the kinetics of the oxidation-reduction reaction, thereby catalyzing the reaction.

- nZVI application can be conducted via injection wells, direct push technology, permeable reactive barriers, liquid atomization, pressure pulse technology, and pneumatic and/or hydraulic fracturing. pH increase occurs due to formation of hydroxyl ions and a decrease in the oxidation-reduction potential (ORP) occurs due to reducing conditions created by iron. The goal when nZVI is delivered to groundwater is to reduce the ORP to less than -400 millivolts to generate faster abiotic reactions (NAVFAC, September 2005). Passivation of nZVI could occur due to ‘natural demand’, particularly when mixed with large volumes of water before injection. Deoxygenation of water before mixing might be required. A ratio of iron to formation soil of 0.004 was found to be effective at a shipyard to achieve nZVI goals of abiotic removal of TCE in DNAPL (NAVFAC, September 2005). However, site-specific demand needs to be established for effective remediation of source areas.
- **Effectiveness –** nZVI is proven to remove TCE and other chlorinated VOCs in groundwater and DNAPL source areas. Effectiveness depends on contact between contaminants and the iron particles. Because migration of injected nZVI might be limited, injection in various areas of interest should be conducted. In source areas multiple injections might be required. However, limited effectiveness of distributing injected solution into low K zones is anticipated. Reaction occurs via beta elimination resulting in formation of ethane in the case of TCE degradation without generation of intermediates such as cis-1,2-DCE or vinyl chloride. Applicability of the process for treating perchlorate has not been studied, although the effect on reducing perchlorate was demonstrated to occur in the treatability study (**Appendix C**). nZVI is not effective on 1,4-dioxane.

- **Implementability –** Manufacturing nZVI and its variations such as EZVI and BNP is commercially available. Implementation can be conducted through existing delivery methods as mentioned above. The important information is to understand the radius of influence at injection points to create an overlapping condition. Injection along the entire vertical contaminant profile is also required to achieve remediation in the zone of interest. Creating nZVI on site reduces the amount of oxidation the iron undergoes ('natural demand') during storage and transport. Distribution of injected ZVI is challenged by subsurface heterogeneity.
- **Cost –** High to very high depending on the volume to be treated.

4.4.1.5.2 Biological Treatment

Biological treatment process options use living organisms such as bacteria or fungi to detoxify or immobilize contaminants in groundwater. These process options are primarily used to convert organic contaminants into nontoxic products.

Enhanced Bioremediation. This general process option covers a wide range of individual biological process options that rely on microbial transformation of organic contaminants under aerobic or anaerobic conditions into benign forms to obtain energy or carbon. Excessively high concentrations of contaminants could be toxic to microbes. Many organic contaminants, including some of the VOCs at LHAAP-18/24 and perchlorate, can be biodegraded under anaerobic (without oxygen) conditions. 1,4-Dioxane is relatively resistant to biodegradation in water and soil (EPA, 2014). Studies indicate that 1,4-dioxane does not biodegrade under anaerobic conditions (ESTCP, 2007). 1,4-Dioxane has been observed to degrade cometabolically under aerobic conditions but most of the work has been in microcosm studies or pilot studies (Zenker et al. 2004, and Lippincott et. al, 2015). The activity of microorganisms is greatly affected by pH, redox potential, temperature, oxygen content, and most importantly, nutrient availability. These conditions can be manipulated to achieve optimal conditions for microbial activity, accelerating the biodegradation of the target contaminants. The conditions are manipulated through the addition of nutrients and/or electron acceptors or donors. After anaerobic bioremediation of VOCs and perchlorate, institution of aerobic conditions in the aquifer with the addition of organic substrate would be required to enhance the potential cometabolic biodegradation of 1,4-dioxane.

A treatability study to assess effectiveness of microbial degradation of VOCs and perchlorate under anaerobic conditions was conducted at SiRem (Ontario, CA, 2014) (**Appendix C**). The testing was conducted on soil and groundwater material received from the area of MW21, representing moderately impacted areas within the dissolved plume migration zones. The results presented in **Appendix C** indicate that enhanced biodegradation is effective with the addition of lactate or emulsified oil as an electron donor. However, the subsurface media conditions had to be adjusted including buffering to improve the pH to near neutral and bioaugmenting with KB-1 Plus® to enhance biodegradation of TCE and its daughter products. The process suffered from the need to adjust the pH on multiple occasions and bioaugmenting at least on two occasions to enhance bacterial population and degrade cis-1,2-DCE. Complete degradation of MC occurred without the addition of organic substrate under strict anaerobic conditions, implying that native microorganisms capable of fermenting MC are readily available in the subsurface but it is hindered by the lack of strict anaerobic conditions and likely the low ambient pH levels. Perchlorate degradation occurred very rapidly once organic substrate was added under the

presence of native microbial populations. The laboratory treatability studies in microcosms could not evaluate the limitations imposed by the presence of contaminants in fine-grained soils and the heterogeneity of the site.

- **Effectiveness –** In situ anaerobic biodegradation is effective for the degradation of VOCs and perchlorate in low oxygen conditions in a permeable media that enhances the continuing delivery of nutrients to the bacteria. The primary challenge for in situ biological treatment is to effectively introduce the bacteria (if bioaugmentation is necessary) and nutrients to the affected areas and ensure adequate mixing and contact. pH buffering was determined to be necessary to enhance biodegradation of CoCs. The rate of destruction is typically slower than other competing processes, but fewer and less toxic byproducts result if complete biodegradation occurred. The vast amount of chloride ions that would be produced through enhanced bioremediation would likely reduce the effectiveness of biodegradation. High concentrations of CoCs (e.g., within DNAPL areas) can be toxic. Anaerobic conditions are not supportive of 1,4-dioxane degradation (ESTCP, 2007).
- **Implementability –** Enhancing the biological activity may be difficult in some of the low permeability soil at LHAAP-18/24 because of complications associated with the delivery of nutrients. Equipment and expertise are readily available and treatability testing provided the proof of concept that this technology works at this site but degradation can take time particularly for chlorinate ethenes. Creation of reducing conditions to enhance anaerobic biodegradation of CoCs could result in mobilization of arsenic from soil to groundwater. Additionally, capture of extraction trenches of the bio-front could result in biofouling of the extraction trenches and operational difficulties. These considerations should be evaluated before implementation of this technology.
- **Cost –** Low to moderate.

Phytoremediation. This general process option covers a wide range of individual plant species to remove VOCs and metals from the subsurface via plant uptake and release to the environment.

- **Effectiveness –** Phytoremediation could be effective for shallow contamination but is unlikely to be effective at the depth of groundwater at the site. The rate of removal of VOCs, 1,4-dioxane, or metals is too slow to be effective. This process is not known to be effective for perchlorate.
- **Implementability –** Planting trees is a straightforward process.
- **Cost –** Low to moderate.

4.4.1.5.3 Summary of In Situ Treatment Process Options

There are numerous in situ groundwater treatment process options available. The presence of daughter compounds for VOCs such as 1,2-DCE detected during the various rounds of groundwater monitoring indicates that NA is occurring in the groundwater at some monitoring wells. Because MNA is the least disruptive technology, MNA is retained as a remediation option for regions beyond the active groundwater removal area and/or as a supporting process option but not a primary process option.

The effectiveness of air sparging/soil vapor extraction and PRB process options for treatment of LHAAP-18/24 groundwater may be limited by site geology or hydraulic conditions (preferential transport pathways limits effectiveness), contaminant characteristics (air sparging is not effective for perchlorate and metals), or the degree of required long-term maintenance (for reactive barriers). In situ chemical oxidation is considered a fast and efficient process with respect to the VOCs and 1,4-dioxane in LHAAP-18/24 groundwater and treatability studies performed for groundwater from other areas at LHAAP identified this option as a viable alternative, but this process is not effective for perchlorate and metals and has its limitations for high VOC concentrations. In situ enhanced bioremediation has been shown to be effective on chlorinated solvents and perchlorate, but is less proven for 1,4-dioxane. Its effectiveness in areas with extreme VOC concentrations is uncertain due to the possibility that byproducts will be produced at concentrations detrimental to the microbial population, but that can be addressed through careful or targeted application of the bioremediation amendments. In situ thermal treatment could be promising for areas of very high concentrations, areas where 1,4-dioxane is present, and in heterogeneous subsurface conditions; however, it should be avoided in the vicinity of the HDPE liners, and its cost is typically very high. Electrokinetics could be implemented effectively in heterogeneous formations to treat not only organic contaminants but also ionic contaminants such as perchlorate and metals. However, the process is slow and in most situations, on site treatment of mobilized contaminants would be required, increasing process complexity and enhanced electrokinetics applications are required to overcome process limitations and improve the opportunity for successful removal and treatment of contaminants. Nanotechnology in the form of nZVI will likely be successful in remediating groundwater as long as distribution is achieved, but it is not effective on 1,4-dioxane. EZVI produces conditions for biodegradation in addition to abiotic degradation ZVI is capable of achieving, but treatability testing did not reveal that EZVI is effective in treating site contaminants.

Out of these in situ options, ISB is favored because it is cost effective and is a proven technology for chlorinated VOCs and perchlorate as has been demonstrated by the treatability testing, although issues such as arsenic mobilization, biofouling in extraction trenches, and its limited effectiveness on 1,4-dioxane need to be considered in the design and implementation of this process. Therefore, ISB will be retained as the primary representative in situ treatment option for remedial alternative development. ERH will not be retained for possible use for general groundwater remediation because this technology is very expensive for dilute concentrations and large volumes. However, it can be retained as a possible remediation technology for localized high concentrations of 1,4-dioxane near monitoring wells 120/MW-14 and MW-16 (see Supplemental to Updated PSI Report, **Appendix B**). Electrokinetics will not be retained for dilute concentrations and large volumes of contaminated groundwater because it is expensive and requires surface treatment technologies to be developed and implemented. nZVI could be used to treat groundwater; however, due to the large area of contaminated groundwater and limited migration potential of nZVI, this technology is best suited for creation of reactive barriers rather than to treat groundwater in a localized application format. Therefore, nZVI will not be retained.

4.4.1.6 Ex Situ Treatment

Ex situ treatment technologies provide varying levels of water treatment following extraction or collection of the water. These technologies are applied to reduce the volume, mobility, or

toxicity of recovered groundwater. Although ex situ treatment technologies considered are physical/chemical, thermal, and biological, they have been grouped into two process options under an on-site treatment technology – the existing treatment system with modifications as may be required, and a new mobile or skid-mounted system near the extraction point.

4.4.1.6.1 New Treatment Plant

A small, skid-mounted or mobile treatment plant could be built near the point of groundwater extraction or to replace a portion of the existing GWTP to make the plant more efficient, automated, and designed for the extraction volumetric rate (e.g., 50 gpm). The treatment system would be designed for removal of the CoCs from the extracted groundwater. Chemical precipitation or metals substitution could remove the metals. GAC or air stripping could remove the VOCs. Ion exchange or biological units could remove the perchlorate and if required, HiPOx^{TM} or advanced oxidation could remove 1,4-dioxane.

- **Effectiveness –** The new system could be very effective. All of the considered technologies for the removal of metals, VOCs, and perchlorate are proven effective and are used at an existing treatment plant at LHAAP. Technologies for the removal of 1,4-dioxane have been proven effective on other sites, but these technologies require high maintenance. The use of smaller units provide less operational flexibility and may expect deviations more often. However, this option could be effective.
- **Implementability –** The implementation of this option is more difficult than that of the existing treatment plant. A few studies would be needed to design the plant to meet the treatment objectives. This option is still reasonably easy to implement.
- **Cost –** High. The capital costs of this option are considerably greater than that of the existing plant. However, it is expected that the operational costs are less for the new treatment plant compared to the existing GWTP.

4.4.1.6.2 Existing Groundwater Treatment Plant

This facility, which is currently processing contaminated groundwater from LHAAP-18/24 and LHAAP-16, includes unit operations such as neutralization, precipitation, air stripping, and biological reduction. The effluent from the plant is currently discharged to Harrison Bayou or used for irrigation at LHAAP-18/24 to enhance contaminant removal. Addition of processes to remove 1,4-dioxane may be required. These technologies, such as advanced oxidation, are commercially available.

- **Effectiveness –** The existing plant is currently treating groundwater. The hydraulic capacity of the plant has not been met yet, so additional flow could be effectively handled. The discharge requirements are routinely met, with some occurrences of perchlorate exceeding the current effluent limit for perchlorate, in general, indicating an effective operation. During these perchlorate excursions, discharge to Harrison Bayou would not take place. The INF Pond, which was historically used for temporary storage, could be re-deployed to manage discharge of treated groundwater when discharge to Harrison Bayou is not possible (e.g., due to low flow or treated groundwater quality exceeding discharge limits) and release to LHAAP -18/24 via the sprinkler system is not possible (e.g., during periods of heavy

rainfall). The effectiveness of advanced oxidation technologies for the removal of 1,4-dioxane is established.

- **Implementability –** The existing plant is already operational. It is operating below current design capacity, so additional extraction wells could be added. Depending on the composition of the additional site groundwater sent to the plant, it is possible that no revisions to the plant would be necessary but this will be evaluated on a case by case basis. For example, current 1,4-dioxane concentrations passing through the plant meet the discharge limit established for Harrison Bayou and Caddo Lake. However, should treatment for 1,4-dioxane be deemed necessary, then modifications to the GWTP would be required. The existing GWTP requires upgrade or replacement of a few major items, such as the FBR tank (e.g. insulation and heat tracing), belt press, compressors, etc.
- **Cost –** Moderate to High dependent on number of units replaced or upgraded and whether advanced oxidation processes are added for 1,4-dioxane treatment.

4.4.1.6.3 Summary of Ex Situ Treatment Process Options

The use of a new treatment plant and the existing LHAAP GWTP will be retained. The existing GWTP has the capacity to take on additional influent volume and it is already effectively operational. Additional upgrades and high maintenance would be required to maintain operational effectiveness and reliability of the existing GWTP. The addition of advanced chemical oxidation for the removal of 1,4-dioxane might be required. However, because of the age and condition of the existing GWTP, the new treatment plant is used to develop remedial alternatives.

4.4.1.7 Disposal

Disposal technologies provide the means to handle the treated discharge from any GWTP. The technologies considered for LHAAP-18/24 are surface water discharge, irrigation, and reinjection. The INF Pond could be deployed to manage discharge of treated groundwater when discharge to Harrison Bayou is not possible (e.g., due to low flow or treated groundwater quality exceeding discharge limits) and release to LHAAP -18/24 via the sprinkler system is not possible (e.g., during periods of heavy rainfall).

Disposal also applies to final disposition of treated vapor generated from air sparging/soil vapor extraction or thermal treatment. The treated or untreated vapor will be discharged to the atmosphere and no additional evaluation of disposal of vapor will be included.

4.4.1.7.1 Surface Water Discharge

Surface water discharge disposes of treated wastewater into a surface water body, stream, or river. Currently, the existing treatment plant discharges to Harrison Bayou.

- **Effectiveness –** This process option is an effective method for disposal of water if the requisite discharge limits can be met. The current treatment system discharges to Harrison Bayou through a monitored point. The effluent limits could be revised in the final ROD and those new limits will need to be achieved to allow discharge to surface water.

- **Implementability –** A discharge point has been established and the infrastructure for the existing water treatment plant allows discharging through this point; therefore, this process option could be easily implemented.
- **Cost –** Low.

4.4.1.7.2 Irrigation

Irrigation disposes of treated wastewater by irrigating vegetation in an approved area. Currently, the existing treatment plant releases treated water via an existing irrigation system to areas of LHAAP-18/24.

- **Effectiveness –** This process option is an effective method for disposal of water when natural flows in Harrison Bayou are insufficient to support direct discharge. The flow rate for irrigation is limited by runoff limitations.
- **Implementability –** The infrastructure for the existing water treatment plant for discharging by irrigation exists; therefore, this process option could be easily implemented.
- **Cost –** Low.

4.4.1.7.3 Reinjection

Reinjection disposes of treated wastewater by reinjecting water into the subsurface. Currently, the existing treatment plant is allowed to reinject treated wastewater at selected ICTs following TCEQ requirements. However, reinjection of treated wastewater has not been performed at the GWTP since 2012 and resumption of the practice is unlikely due to potentially deleterious risks.

- **Effectiveness –** This process option is an effective method for disposal of water when natural flows in Harrison Bayou are insufficient to support direct discharge. The reinjected groundwater has the potential to flush out additional contaminants between the injection and extraction sites, but caution should be taken to ascertain that contaminants will not be driven off-site or downward to the Wilcox Formation.
- **Implementability –** The existing water treatment plant is currently connected to release treated groundwater to two ICTs; therefore, this process option could be easily implemented.
- **Cost –** Low.

4.4.1.7.4 Discharge to the INF Pond

Discharge of treated groundwater to the INF Pond is an available option when discharge to Harrison Bayou is not possible either because there is little to no flow in Harrison Bayou or the treated water quality exceeds the discharge limits. Currently, the existing treatment plant is capable of releasing treated wastewater to the INF Pond. However, there is no current mechanism for conveying the water from the INF Pond back to the GWTP, as might be required when the water in the INF Pond exceeds the discharge limits. Therefore, a pumping system would need to be designed and implemented before this discharge option becomes viable.

- **Effectiveness –** This process option is an effective method for disposal of treated water when natural flows in Harrison Bayou are insufficient to support direct discharge or when the concentrations in the effluent are higher than the discharge limits.

- **Implementability –** The existing water treatment plant is currently connected to the INF Pond and groundwater can be released; therefore, this process option could be easily implemented. However, a pumping system to convey INF Pond water back to the GWTP would be required.
- **Cost –** Low to moderate.

4.4.1.7.5 Summary of Disposal Process Options

Surface water discharge, discharge to the INF Pond, and irrigation are retained since they are currently part of the operation of the existing GWTP, which has been retained as a process option. Release of groundwater via reinjection has ceased because control over migration of CoCs to outside the containment is not present.

4.4.1.8 Summary of Representative Groundwater Process Options

The following representative GRAs, technologies or process options are retained for groundwater:

- No action
- LUCs
- Containment by slurry wall with soil cover
- In situ treatment by ISB or MNA
- ERH targeting high 1,4-dioxane areas as a contingency remedy
- Removal by vertical extraction well and interception trench
- Treatment in the existing GWTP with upgrades and potential addition of a 1,4-dioxane treatment process as a contingency remedy
- Treatment in a new GWTP including potential treatment for 1,4-dioxane.
- Disposal by surface water discharge, to INF Pond, or via irrigation

Detailed analyses of these remedial alternatives are included in **Section 5.0**.

4.4.2 Saturated (Secondary Source) Soil Source Areas

In the following subsections, soil process options are evaluated to address residual contamination in the saturated soil that has the potential to be a long-term source of contamination to the groundwater (i.e., DNAPL areas). The evaluation is presented graphically in **Figure 4-2**. As discussed previously, the LUCs and containment options are similar to the groundwater medium and will not be repeated here but are shown on **Figure 4-2**. It is assumed that this section applies to the two residual DNAPL areas identified during PSI and PSI Addendum investigation (AECOM, 2013 and 2014) conducted. These areas include the former UEP area extending approximately 35,500 ft^2 and the former ACD area extending approximately 5,000 ft^2 with a depth of impact to approximately 50 feet in the former UEP area and to 30 feet in the former ACD area.

4.4.2.1 No Action

The "no action" process option does not provide additional remediation, maintenance, or security activities at contaminated soil areas at LHAAP-18/24. This process option is retained as a baseline with which other remediation alternatives are compared.

- **Effectiveness –** This response action should not have negative long-term impacts on human health and the environment; however, it may impact the duration that some groundwater remedy components must be implemented.
- **Implementability –** No implementation is required.
- **Cost –** None.

4.4.2.2 Removal

The removal GRA consists of technologies that remove contaminated soil for treatment and/or disposal or entails mobilization and removal of DNAPL for treatment and/or disposal. The removal technology considered is excavation with a process option of conventional excavation or surfactant flushing for DNAPL followed by extraction.

4.4.2.2.1 Excavation

Conventional Excavation. This excavation method uses a variety of conventional excavation equipment to remove debris, soil, and other buried waste. The equipment includes excavators, track loaders, bulldozers, and tool carriers of differing sizes with attachments or manipulators suitable for dealing with a varied waste profile. This equipment can be used individually or together as circumstances dictate. It is considered applicable to the contaminated soil at LHAAP-18/24. It can be used for both shallow and deep soil.

- **Effectiveness –** Conventional excavation equipment is applicable to the LHAAP-18/24 soil contamination. The equipment has consistently proven reliable and effective for removal of soil and other media in hazardous and non-hazardous applications for decades. Various attachments can increase the versatility of the equipment, allowing their use with a wide range of wastes. Ancillary equipment for screening, sorting, and segregation can be effectively integrated with conventional excavation equipment.

  The hazards to operators, in addition to the normal excavation hazards, come from exposure to contaminated media. Misting or fixative agents can reduce fugitive dust emissions during excavation. PPE can reduce or eliminate exposure from inhalation/ingestion or dermal contact.
- **Implementability –** Conventional excavation is readily implementable, and the equipment, attachments, and operators are widely available. The equipment can be readily adapted to the material and conditions at the site. However, excavation into the saturated zone would require dewatering. Also the depth of the excavation would increase overall project costs via the additional excavation volumes associated with benching the slopes for safety or the use of shoring.
- **Cost –** Moderate to high depending on the volume requiring removal, the depth of excavation, and the amount of water requiring separation and processing.

4.4.2.2.2 Surfactant Flushing and DNAPL Extraction

This process option uses chemical surfactants injected in the subsurface within source areas (e.g., DNAPL areas) to mobilize DNAPL into the groundwater followed by extraction of groundwater for removal of source of contamination. The equipment includes use of direct push injection tools or injection through vertical wells either existing or installed for this process. Extraction of groundwater will occur via extraction wells installed for this process to capture mobilized contaminants and prevent migration to undesirable areas. It is considered applicable to the contaminated soil at LHAAP-18/24 but treatability testing to select the type and concentration of surfactant is recommended. It can be used for both shallow and deep soil.

- **Effectiveness –** Injection and extraction equipment is applicable to the LHAAP-18/24 soil contaminants. Similar equipment for extraction of groundwater has consistently proven reliable and effective for removal of groundwater at LHAAP-18/24. The surfactants are typically not hazardous to workers at the site. Extracted groundwater containing very high concentrations of VOCs must be managed in a closed loop system to minimize loss of vapors to the atmosphere and exposure of workers. If not designed well, surfactant flushing could result in uncontrolled NAPL migration to unintended locations. The distribution of surfactants could be uneven between coarse-grained and fine-grained soils (low K zones) with the majority of surfactants flowing through coarse-grained soils, resulting in poor mobilization of fine-grained soil DNAPL, which contains the majority of residual DNAPL.
- **Implementability –** Injection of chemicals and extraction of groundwater are readily implementable, and the equipment, attachments, and operators are widely available. The equipment can be readily adapted to the material and conditions at the site.
- **Cost –** Moderate to high.

4.4.2.2.3 Saturated Soil Summary of the Removal Process Option

Conventional excavation equipment is not carried forward because of the difficulties that would be encountered at the desired depths of excavation, the large volumes of soil that would be excavated increased by the need to slope the ground for deeper excavations, the potential for increasing in emissions of VOCs during excavation, and the high cost associated with off-site hauling and disposal. Surfactant flushing and extraction to reduce source area mass is carried forward for source reduction despite the uncertainty in delivering surfactants to low permeability zones for removal of trapped DNAPL.

4.4.2.3 In Situ Treatment

In situ treatment technologies provide varying levels of saturated soil treatment and reduce the mobility and/or toxicity of the contaminants associated with soil and present as DNAPL. The in situ treatment technologies under consideration are physical/chemical and biological treatments.

4.4.2.3.1 Physical/Chemical Treatment

MNA, air sparging/soil vapor extraction, in situ oxidation, permeable reactive barriers, thermal treatment, surfactant flushing, electrokinetics, and nanotechnology are process options considered potentially applicable to the saturated soil source areas at LHAAP-18/24.

Monitored Natural Attenuation. MNA is a remedial process option that will achieve the cleanup levels over time. Natural subsurface processes such as dilution, volatilization, biodegradation, adsorption, and chemical (abiotic) reactions with subsurface materials are monitored to confirm their progress in reducing contaminant concentrations. **Appendix A** provides an evaluation of the ongoing NA at LHAAP-18/24. The VOCs and perchlorate are amenable to MNA.

- **Effectiveness –** MNA is considered under CERCLA on a case-by-case basis. USEPA guidance has been developed to aid in the selection of this process option for VOCs. MNA has been selected for a number of CERCLA sites. MNA is not effective for source areas when DNAPL is present due to toxicity of high concentrations of VOCs and rate limitations associated with dissolution rates of contaminants from DNAPL to groundwater. MNA for source areas could be achieved as a polishing step after implementation of other effective remedies.
- **Implementability –** Significant groundwater sampling and analyses must be performed to confirm that conditions are suitable for NA and to establish a monitoring network.
- **Cost –** Low to moderate but could be high with specialty tests and if MNA takes a long time to achieve the RAOs.

Air Sparging/Soil Vapor Extraction. This process option is designed to remove VOCs from the groundwater by volatilizing these contaminants through the introduction of air. Air is introduced into the groundwater, assisting in the volatilization of those organics in solution in the groundwater. Extraction wells are installed into the vadose zone and a vacuum is drawn on these wells. The extraction system draws off the organic-laden air that was bubbled through the groundwater in addition to any vapors that exist in the soil pore spaces. The volatilized contaminants can then be drawn from these extraction wells and treated. This process can be used in those areas where VOCs exist in the groundwater and the vadose zone above this groundwater is relatively permeable but not effective in DNAPL areas.

- **Effectiveness –** This process is very effective on highly volatile contaminants (e.g., TCE) and highly permeable formations. It is incompatible with certain soil types, and high humic content inhibits volatilization of contaminants. Implementation at LHAAP-18/24 is complicated by the subsurface heterogeneity and high clay content soil that may limit the effectiveness of air sparging by retarding the movement of air and vapors through the soil column. The presence of discontinuous high-permeability zones can result in preferential air flow paths, limiting the effectiveness. Air sparging is not effective for remediating perchlorate or metals, and is less effective for remediating 1,4-dioxane compared to VOCs.
- **Implementability –** Vapor extraction and air sparge equipment is readily available and commercial vendors are available to design and operate these systems. This process has been used at many hazardous waste sites in relatively homogeneous media. Organics that are removed from the vapor extraction wells require ex situ treatment. Site characterization and modeling are required to determine the proper location of the injection and extraction wells and extraction rates.
- **Cost –** Low to moderate.

In Situ Oxidation. Contaminated media are treated through the addition of oxidizers, such as potassium permanganate, hydrogen peroxide, or activated persulfate, which convert the contaminants to a less mobile or toxic form. This process option is applicable to VOCs such as TCE, and 1,4-dioxane.

- **Effectiveness –** In situ oxidation is effective on contaminants in a relatively homogeneous and porous medium. The shallow groundwater zone at LHAAP-18/24 is largely non-homogenous, of variable porosity, and discontinuous. Chemical oxidation is most effective for VOCs (particularly TCE) and is considered a suitable approach for the primary CoCs at LHAAP-18/24 (MC and TCE). Some chemical oxidants are effective on 1,4-dioxane, such as Fenton's reagent and activated persulfate, but others are not effective, such as permanganate. Multiple applications might be required to treat DNAPL areas. Precipitates formed during the oxidation process could decrease effective permeability and make the process less effective. Chemical oxidation is not effective for treatment of metals or perchlorate, and certain oxidants are not effective on chlorinated alkanes such as 1,2- DCA. The great amount of mass of CoCs in DNAPL requiring oxidation makes this process ineffective.
- **Implementability –** This process option is readily implementable but concerns regarding distribution and exposure of the contaminants to the chemical agents exist. An additional concern is the release of excess reactants or byproducts to the environment. In-situ applications of these processes are well established. A recent USEPA evaluation by their Technology Innovation Office concluded that the application of in situ oxidation is highly dependent on the delivery system and application for remediation of DNAPL is not favored over other technologies (USEPA, August 2006).
- **Cost –** Moderate.

Permeable Reactive Barriers. PRBs can be a physical/chemical or biological treatment option. A reactive barrier or gate is a permeable wall containing reactive media that is constructed across the path of a contaminant plume. As contaminated water passes through the wall, the contaminants are removed or degraded, allowing uncontaminated water to emerge on the downgradient side. Reactive barriers are usually installed through adaptation of conventional construction methods for impermeable barriers such as open trenches, polymer slurry trenches, and overlapping caissons. Reactive barriers may be constructed from a variety of materials including ZVM, GAC, biological material, other sorbents, or a combination. These materials treat contaminants through a combination of mechanisms, including adsorption, chemical reduction, and biodegradation. Reactive barriers are used to prevent migration of contaminants off-site or to nearby receptors and requires contaminated groundwater to pass through the barrier. Therefore, this technology is not applicable to DNAPL source areas, which are primarily not mobile.

- **Effectiveness –** The effectiveness of this process depends greatly on the contaminants, the reactive media, site hydrology, and site geochemistry and highly depends on migration of contaminants through the barrier. DNAPL migration through the barrier is unlikely to occur at this site. Reactive media clogging and exhaustion causes the need for periodic replacement. There are concerns over the longevity of the reactive media given uncertain and changing chemical and physical conditions and the potential high load of CoCs through the gate that could exhaust the reactive barrier material rapidly. Not effective on metals.

- **Implementability –** PRBs are not applicable for DNAPL remediation.
- **Cost –** Not applicable for DNAPL remediation.

Thermal Treatment. Heating the subsurface can effectively and quickly volatilize large quantities of VOCs, including those in the form of non-aqueous phase liquid. Available technologies include ERH, steam injection, and conductive heating, which are typically coupled with a soil vapor extraction system to capture VOCs. ERH delivers electricity to the subsurface through an array of electrodes. The heat generated by electrical resistance typically can raise subsurface temperatures to around the boiling point of groundwater. The steam produced from the groundwater serves as a medium to carry out volatilized VOCs. Steam injection involves the ex situ generation of heat and steam, which is delivered to the subsurface through new or existing wells. Similar to ERH, VOCs are volatilized and carried to the soil vapor extraction system by steam. Conductive heating involves applying heat and vacuum simultaneously to subsurface soils with an array of vertical heater/vacuum wells. Heat generated from heating elements is transferred to the subsurface largely via thermal conduction and radiant heating. In addition, heat can promote in situ biological activity in two ways. First, biological activity is boosted by moderately high temperatures (30°C) found at the periphery of the heated area during active thermal treatment, and throughout the heated area as it cools. Second, high temperatures increase the solubility of DNAPL, resulting in increase in contaminant concentrations in the dissolved form that the microbes are able to use.

- **Effectiveness –** Removal of TCE, MC, and other VOCs is anticipated to be effective in high concentration areas, where DNAPL may exist. Thermal treatment does not suffer from the same limitations of subsurface heterogeneity like the other in-situ technologies. High flow zones have been problematic because they transport the heat away from the targeted area more quickly than low K zones. However, temperature distribution in the subsurface can be made more uniform based on the duration of application of thermal treatment. VOC concentrations in thermally-treated groundwater may reach an asymptote; therefore, a follow-up treatment method is likely to be necessary to reach RAOs, including MNA. Thermal technology is not anticipated to have an effect on perchlorate (an ion) or metals.
- **Implementability –** Additional site characterization to better define DNAPL (especially with ERH because of the cost of installing electrodes) has been conducted and site samples were collected and tested for total organic carbon and thermal resistivity by the technology vendor. The results (**Appendix C**) indicated that the site is amenable to thermal treatment. A significant disadvantage to thermal treatment is that it may compromise the HDPE liner installed along the northern and western perimeters of the site, as well as the network of HDPE piping in the shallow soil (which carries groundwater to the treatment plant). Affected HDPE components could be replaced following thermal treatment, but replacement costs would be significant for the liner. During the thermal treatment, which could take place over several months to over a year (depending on the actual size of the area of treatment), the possibility of compromising the liner could exacerbate the migration of perchlorate towards Harrison Bayou. Alternatively, the treatment could be operated at lower temperatures or operated away from the liner; both would lower overall effectiveness of the technology if certain target areas are not treated.
- **Cost –** High to very high.

Electrokinetics. Induced low voltage DC between the electrodes placed in the ground in an open flow arrangement causes water, ions, and colloids to migrate to the electrodes. Groundwater is the conductive medium. Movement occurs under induced potential via electroosmosis, electromigration, and electrophoresis. The advantages of electrokinetics is its effectiveness in fine-grained soils and for in situ treatment of heavy metals. Technology limitations include solubility of contaminants to be treated, corrosion of anode material, migration rates are slow, change in ambient pH could lead to precipitation and fouling of the cathode, and the presence of large quantities of iron or iron oxides can reduce removal efficiencies. Enhanced electrokinetics techniques attempt to reduce these limitations and improve process performance. Extraction of fluids mobilized to the electrodes for above ground treatment would be required which increases the complexity and cost of the process. The Lasagne™ process developed in cooperation between the USEPA and a private consortium was demonstrated to treat TCE DNAPL in tight clay soil with removal efficiencies of 98% in soil up to 15 feet bgs (GWRTAC, 1997). TCE was mobilized into carbon-containing treatment zones where it was trapped. The process involves creating in situ reactive zones to treat CoCs in situ without extraction. The Lasagne™ process could overcome many of known limitations of electrokinetics and avoids above ground remediation needs.

- **Effectiveness –** Removal of TCE, MC, and other VOCs is anticipated to be effective in high concentration and fine grained soil areas, including where DNAPL may exist. Some volatilization of VOCs could occur. Effectiveness depends on a lot of factors such as grain size, ionic strength (cation exchange capacity and salinity), contaminant concentrations, soil type and structure, and presence of high concentrations of other naturally occurring material such as iron. On its own, electrokinetics has severe limitations such as precipitation (fouling of) on electrodes, severe pH increase in soil, and solubility limitations of contaminants. The site has a very high iron content and with increasing pH, fouling due to precipitation or iron could compromise the success of the process. Therefore, electrokinetics combined with other technologies (enhanced electrokinetics) would be required to minimize limitations and improve opportunity to mobilize contaminants for removal or in situ treatment (e.g., oxidation and bioremediation).
- **Implementability –** Prior to implementing full scale treatment, it may be appropriate to perform additional soil characterization to better define potential limiting factors. Studies include field electrical conductivity surveys, pH and electrical conductivity of pore water, major dissolved ion concentrations in groundwater/pore water, buffering capacity and geochemistry of soil (CEC and salinity). Treatability testing to ensure that the system design delivers as expected might be required. Areas where ICTs are present may not be candidates for remediation as these ICTs will interfere with contaminant migration and continuity of induced currents. Although these ICTs could be used to extract mobilized contaminants for treatment. However, this approach requires a focused study to understand the dynamics and limitations.
- **Cost –** High to very high.

Nanotechnology. Remediation of DNAPL using nanoparticles containing nZVI or EZVI is a promising technology, which has been implemented on several sites (EPA, December 2007). The success will depend on delivering the right dose at the right place to allow contact between the contaminant and the iron particles. nZVI application can be conducted via injection wells, direct

push technology, permeable reactive barriers, liquid atomization, pressure pulse technology, and pneumatic and/or hydraulic fracturing. Treatment of perchlorate by nZVI is indirect and occurs by enhancing the geochemistry of the environment where nZVI is introduced to biodegrade perchlorate by indigenous bacterial populations. Treatment of metals such as arsenate, selenite, and hexavalent chromium occurs in the presence of nZVI. nZVI is not effective in treating 1,4-dioxane.

A treatability study to assess effectiveness of ZVI (0.1 to 5 um) and EZVI was conducted at SiRem (Ontario, CA, 2014) (**Appendix C**) to determine effectiveness to treat highly impacted saturated site areas that can be characterized to contain DNAPL. The results presented in **Appendix C** indicate that EZVI was not effective at various dose levels (0.004, 0.03, 0.1, and 0.2 g EZVI to g formation) and no degradation of VOCs or perchlorate occurred even when the reactors were bioaugmented with specific degrading bacteria (KB-1 Plus®). ZVI testing produced more promising results with degradation occurring at all four doses but the rate was quicker for higher ZVI doses compared to the lower ZVI doses. TCE degradation without the occurrence of daughter products was observed to occur readily. Significant reduction in MC and perchlorate concentrations was also observed likely associated with fermentation of MC and use of hydrogen by native bacteria for reduction of perchlorate. The tests were conducted on micron sized ZVI but it would be expected that nZVI to be as or more effective than micron-sized ZVI.

- **Effectiveness –** nZVI is proven to remove TCE, MC, and other chlorinated VOCs in DNAPL source areas. Effectiveness depends on contact between contaminants and the iron particles. Because migration of injected nZVI might be limited, injection in various areas of interest should be conducted. In source areas multiple injections might be required to achieve desired remediation goals. Reaction occurs via beta elimination resulting in formation of ethane in the case of TCE degradation without generation of intermediates such as cis-1,2-DCE or vinyl chloride. Applicability of the process for treating perchlorate has not been studied, although the effect on reducing perchlorate was demonstrated to occur in the treatability study (**Appendix C**). nZVI is not effective on 1,4-dioxane.
- **Implementability –** Manufacturing nZVI and its variations such as EZVI and BNP is commercially available. Implementation can be conducted through existing delivery methods as mentioned above. The important information is to understand the radius of influence at injection points to create an overlapping condition. Injection along the entire vertical contaminant profile is also required to achieve remediation in the zone of interest. Creating nZVI on site reduces the amount of oxidation the iron undergoes (‘natural demand’) during storage and transport. Distribution of injected ZVI is challenged by subsurface heterogeneity.
- **Cost –** High to very high depending on the volume to be treated.

4.4.2.3.2 Biological Treatment

Biological treatment process options use living organisms such as bacteria or fungi to detoxify or immobilize contaminants in groundwater. These process options are primarily used to convert organic contaminants into nontoxic products.

Enhanced Bioremediation. This general process option covers a wide range of individual biological process options that rely on microbial transformation of organic contaminants under aerobic or anaerobic conditions into benign forms to obtain energy or carbon. Many organic

contaminants, including some of the CoCs at LHAAP-18/24 and perchlorate, can be biodegraded under anaerobic (without oxygen) conditions. However, 1,4-dioxane is relatively resistant to biodegradation in water and soil (EPA, 2014). Studies indicate that 1,4-dioxane does not biodegrade under anaerobic conditions (ESTCP, 2007). 1,4-Dioxane has been observed to degrade cometabolically under aerobic conditions, but most of the work has been in microcosm studies or pilot studies (Zenker et al. 2004 and Lippincott et. al, 2015). The activity of microorganisms is greatly affected by pH, redox potential, temperature, oxygen content, and most importantly, nutrient availability. These conditions can be manipulated to achieve optimal conditions for microbial activity, accelerating the biodegradation of the target contaminants. The conditions are manipulated through the addition of nutrients and/or electron acceptors or donors. DNAPL is likely toxic to microbes and if biodegradation occurs at the periphery of the DNAPL areas, the process is very slow such that its effectiveness is minimal.

- **Effectiveness –** In situ anaerobic biodegradation is not effective for DNAPL which can be highly toxic. While biodegradation could be enhanced at the perimeter of the DNAPL zones, the duration would be very large to achieve RAOs. Effectiveness is also limited by the ability to distribute the substrate into the heterogeneous subsurface material.
- **Implementability –** Enhancing the biological activity may be difficult in some of the low permeability soil at LHAAP-18/24 because of complications associated with the delivery of nutrients and within high concentration areas (DNAPL) due to toxicity effects. Equipment and expertise are readily available. Treatability testing was not conducted directly in media containing DNAPL; nonetheless, bioaugmentation of an EZVI reactor with KB-1 Plus® did not result in enhancing biodegradation of highly impacted soil. It is believed that the concentrations were toxic to the added microbes. Creation of reducing conditions to enhance anaerobic biodegradation of CoCs could result in mobilization of arsenic from soil to groundwater. Additionally, capture of extraction trenches of the bio-front could result in biofouling of the extraction trenches and operational difficulties. These considerations should be evaluated before implementation of this technology.
- **Cost –** Low to moderate.

Phytoremediation. This general process option covers a wide range of individual plant species to remove VOCs and metals from the subsurface via plant uptake and release to the environment.

- **Effectiveness –** Phytoremediation could be effective for shallow contamination but is unlikely to be effective at the depth of DNAPL in the saturated zone at the site. The rate of removal of VOCs or metals is too slow to be effective and the time for the trees to grow to suitable height (depth of root zone) is long. This process is not known to be effective for perchlorate. Additionally, toxicity of DNAPL to trees would make this option infeasible.
- **Implementability –** Planting trees is a straightforward process.
- **Cost –** Low to moderate.

4.4.2.3.3 Summary of In Situ Treatment Process Options

There are numerous in situ groundwater treatment process options available. Reductions in VOC concentrations via MNA within the DNAPL zones are not likely due to potential toxic effects of DNAPL on bacterial populations. MNA is not retained as a remediation option for DNAPL

areas. However, MNA could be retained as a polishing technology for the DNAPL areas after implementation of other remediation technologies that is effective in treating DNAPL areas.

The effectiveness of air sparging/soil vapor extraction and permeable reactive barrier process options for treatment of DNAPL at LHAAP-18/24 in groundwater may be limited by site geology or hydraulic conditions (preferential transport pathways limits effectiveness), contaminant characteristics (air sparging is not effective for perchlorate and metals), or the degree of required long-term maintenance (for reactive barriers). These technologies are not retained. In situ chemical oxidation could be effective for destruction of VOCs; however, DNAPL remediation via in situ oxidation is unlikely to be effective due to the extremely high demand of oxidants by DNAPL and the inability to achieve oxidant-contaminant contact. Other processes are deemed more favorable for DNAPL remediation than in situ oxidation (USEPA, August 2006). This process is also not effective for perchlorate and metals. Therefore, in situ oxidation is not retained for DNAPL area remediation.

In situ enhanced bioremediation has been shown to be effective on chlorinated solvents and perchlorate. Its effectiveness in areas with extreme VOC concentrations is uncertain due to the possibility that byproducts will be produced at concentrations detrimental to the microbial population and the high VOC concentration is toxic to the organisms. Therefore, biodegradation of source areas is not retained, although enhanced ISB could be implemented as a polishing remedial technology. In situ thermal treatment is promising for areas of very high concentrations. Although, the technology should be avoided in the vicinity of the HDPE liners and its cost is typically very high, this technology will be retained. Surfactant flushing of DNAPL areas (evaluated under “Removal” options) has been proven to be effective with appropriate use of surfactant type and concentration and will be retained. Phytoremediation is not retained due to its lack of effectiveness for DNAPL remediation. Electrokinetics could be implemented effectively in heterogeneous formations to treat not only organic contaminants but also ionic contaminants such as perchlorate and metals. However, in most situations, on site treatment of mobilized contaminants would be required, increasing process complexity and enhanced electrokinetics applications are required to overcome process limitations and improve opportunity for successful removal and treatment of contaminants. Significant studies and treatability testing are required to assure that an understanding of formation limitations are achieved and the process can be designed and implemented with appropriate enhancement to achieve desired endpoints effectively. Nanotechnology in the form of nZVI will likely be successful in remediating source areas as long as sufficient iron is delivered and distribution is achieved. EZVI produces conditions for biodegradation in addition to abiotic degradation ZVI is capable of achieving.

Out of these in situ options, surfactant flushing, ERH, electrokinetics, and nZVI are favored. Surfactant flushing is cost effective and is proven to achieve significant reductions in DNAPL concentrations. Surfactant flushing could be followed with ISB as a secondary technology to further reduce residual concentrations. ERH is retained due to its effectiveness on remediating DNAPL, although the technology is expensive. Electrokinetics when implemented to achieve in situ remediation and avoid above ground treatment could be successful. Use of nZVI to treat source areas has been implemented with success and should be applicable at this site. Use of nZVI provides further enhancement for successful applications. Therefore, surfactant flushing, ERH, and nanotechnology are retained as representative technologies for the in situ treatment option. More detailed evaluation may be appropriate during remedial design to determine the

most effective in situ treatment option given the specific areas of application and the most recent cost information.

4.4.2.4 Ex Situ Treatment

Ex situ treatment technologies provide treatment of excavated soils or extracted DNAPL on site. These technologies are applied to reduce the volume, mobility, or toxicity of recovered material. Although ex situ treatment technologies considered are physical/chemical, thermal, and biological, they have been grouped into one process option under an on-site treatment technology using a skid-mounted system near the extraction point. Treatment of excavated soil containing DNAPL is not considered, as soil excavation was excluded.

4.4.2.4.1 On-Site Skid-mounted Treatment Plant

A skid-mounted or mobile treatment plant could be built near the point of DNAPL extraction. The treatment system would be designed for removal of extracted CoCs either in liquid form (i.e., via surfactant flushing) and or vapor form (i.e., thermal treatment).

Biological treatment methods are not effective at the concentrations of VOCs in extracted groundwater. Thermal treatment methods such as thermal oxidation or incineration can be effective for removal or oxidation of VOCs in vapor phase but the lack of availability, high cost, and complex processes associated with these methods to treat this material makes this process not feasible. Chemical oxidation methods could be effectively implemented to treat extracted DNAPL but requires design, procurement, construction, and operation. GAC can be effective in removing vapor phase and/or liquid phase VOCs extracted via thermal treatment process or surfactant flushing process, respectively, although the cost might be high. Treated extracted groundwater could then be discharged to the GWTP to treat metals and perchlorate. Vapor phase VOCs could be separated using cooling the vapor phase to very low temperatures, using liquid nitrogen or other cryogenic fluid as a refrigerant. The process is applied as a pretreatment stage in the gas treatment phase to reduce excessive loading for final treatment using GAC for example to polish residual VOCs.

- **Effectiveness –** A skid-mount system could be effective for chemical oxidation and thermal treatment but not for biological treatment. Emission controls are required to prevent exposure.
- **Implementability –** The implementation of this option is difficult. A few studies would be needed to design the plant to meet site conditions. Equipment availability and vendor expertise in this area is limited but available.
- **Cost –** Medium to high. The capital cost of this option is considerable. However, there is a potential that the operational costs could be minimized.

4.4.2.4.2 Summary of Ex Situ Treatment Process Options

A new skid-mounted plant will be retained for remedial alternative development. Ex-situ management of extracted DNAPL in liquid or vapor form provides a safe and cost-effective approach.

4.4.2.5 Disposal

The disposal GRA consists of those technologies that provide for the disposal of removed wastes at new or existing, permitted disposal facilities. Both on-site and off-site facilities are evaluated. A selection of on-site facilities versus off-site facilities is made for developing alternatives.

4.4.2.5.1 Off-Site Disposal

Off-site disposal options include off-site treatment and disposal facilities, a RCRA disposal facility, or an industrial landfill. The selection of the disposal facility depends on the waste characteristics.

Treatment, Storage, and Disposal Facility. A TSD facility is a commercial, permitted, off-site facility that is licensed to treat, store, and/or dispose of a variety of waste streams. There are numerous such facilities all over the country offering broad ranges of treatment options, many of which could effectively treat and dispose of the LHAAP-18/24 waste and soil. This option would be used if treatment before disposal is needed such as liquid phase DNAPL (from surfactant flushing).

- **Effectiveness –** A TSD facility is effective at treating and disposing of treated wastes in a permitted, off-site disposal facility.
- **Implementability –** Numerous facilities exist that have and are treating wastes similar to those found at LHAAP-18/24. These facilities are already permitted and licensed to operate. Wastes have to meet the waste acceptance criteria of the receiving TSD facility.
- **Cost –** Moderate to high based on distance to facility and volume of waste generated.

RCRA Disposal Facility. This process option consists of any number of existing disposal facilities that use engineered features such as multilayer liners and caps, leachate detection and collection systems, run-on/-off controls, and intrusion barriers to isolate wastes from human and environmental receptors.

- **Effectiveness –** Disposal involves permanent disposition of the RCRA-generated wastes in a manner that protects human health and the environment. Off-site disposal would include the transportation of generated wastes (e.g., precipitates generated from treatment of extracted surfactant flushed groundwater containing DNAPL) to an approved and licensed facility. This process option is not effective for extracted DNAPL.
- **Implementability –** Readily implementable if the waste acceptance criteria can be met.
- **Cost –** Moderate to high.

Industrial Landfill. An existing industrial landfill can be used to dispose of debris or refuse that is not a RCRA waste or has been decontaminated to acceptable levels. Such a facility is a Class II lined facility permitted to receive industrial, commercial, institutional, land-clearing, and construction/demolition waste. The facility does not accept RCRA-hazardous waste or free liquids. This option would be used to dispose of waste that is considered hazardous to human health and the environment but is not a RCRA-hazardous waste.

- **Effectiveness –** Industrial landfills are effective in isolating low hazard wastes from the environment and human receptors because the waste acceptance criteria severely restrict the type and concentrations of waste that may be disposed.
- **Implementability –** Disposal of the excavated clean wastes or treated wastes would involve transportation and compliance with waste acceptance criteria. An industrial landfill does not accept hazardous soil and/or DNAPL.
- **Cost –** Moderate.

4.4.2.5.2 On-Site Disposal

On-site consolidation is considered as the technology process option for on-site disposal.

Consolidation. Consolidation involves placing treated LHAAP-18/24 soil back into LHAAP areas. The waste is excavated, partially treated on the site if needed, and then placed elsewhere on LHAAP. The contaminants in the treated waste would have to have been destroyed or rendered immobile, making the treated waste better suited for placement. This option precludes the need to transport the treated waste to an off-site disposal facility. A single or multilayer cap would then be placed over the waste. If the waste is fully treated, no special disposal process option is needed.

- **Effectiveness –** Consolidation is effective in isolating the very low hazard wastes from human receptors and the environment. It can limit the area requiring long-term institutional controls. This process is not effective on DNAPL extracted groundwater/soil.
- **Implementability –** Consolidation is used at other hazardous waste sites around the country where off-site disposal options are unavailable or undesirable and where the continued on-site presence of treated waste is not problematic. Given the potential future land uses at the LHAAP, there may be regulatory and public reluctance to moving the waste around the LHAAP.
- **Cost –** Low compared to off-site disposal.

4.4.2.5.3 Summary of Disposal Process Options

RCRA landfill and TSD off-site disposal process options are carried forward for additional consideration until waste streams and volumes are more clearly identified in the alternative development process. Disposal in an industrial landfill is not retained as the generated wastes or extracted DNAPL will likely be hazardous. The on-site disposal option of consolidation is not retained because of the potential regulatory and public concerns about leaving waste on the site after having already removed it, the potential future land uses, and the widespread availability of off-site treatment and disposal facilities.

4.4.2.6 Summary of Representative Process Options for Source Soil in the Saturated Zone

The following representative GRAs, technologies or process options are retained:

- No action
- LUCs

- Containment by slurry wall with soil cover
- In situ treatment by ERH or nanotechnology
- Removal by surfactant flushing and off-site disposal and/or on-site treatment

Development of the remedial alternatives is included in **Section 5.0**.

4.4.3 Unsaturated Soil

In the following subsections, soil process options are evaluated to address residual contamination in the unsaturated soil that has the potential to be a long-term source of contamination to the groundwater via leaching. The evaluation is presented graphically in **Figure 4-3**. As discussed previously, the LUCs and containment options are similar to the groundwater medium and will not be repeated here but are shown on **Figure 4-3**.

4.4.3.1 No Action

The "no action" process option does not provide additional remediation, maintenance, or security activities at contaminated soil areas at LHAAP-18/24. This process option is retained as a baseline with which other remediation alternatives are compared.

- **Effectiveness –** This response action should not have negative long-term impacts on human health and the environment; however, it may impact the duration that some groundwater remedy components must be implemented.
- **Implementability –** No implementation is required.
- **Cost –** None.

4.4.3.2 Removal

The removal GRA consists of technologies that remove contaminated soil for treatment and/or disposal. The removal technology considered is excavation with a process option of conventional excavation.

4.4.3.2.1 Excavation

Conventional Excavation. This excavation method uses a variety of conventional excavation equipment to remove debris, soil, and other buried waste. The equipment includes excavators, track loaders, bulldozers, and tool carriers of differing sizes with attachments or manipulators suitable for dealing with a varied waste profile. This equipment can be used individually or together as circumstances dictate. It is considered applicable to the contaminated soil at LHAAP-18/24. It can be used for both shallow and deep soil.

- **Effectiveness –** Conventional excavation equipment is applicable to the LHAAP-18/24 soil contamination. The equipment has consistently proven reliable and effective for removal of soil and other media in hazardous and non-hazardous applications for decades. Various attachments can increase the versatility of the equipment, allowing their use with a wide range of wastes. Ancillary equipment for screening, sorting, and segregation can be effectively integrated with conventional excavation equipment. The hazards to operators, in addition to the normal excavation hazards, come from exposure to contaminated media.

Misting or fixative agents can reduce fugitive dust emissions during excavation. PPE can reduce or eliminate exposure from inhalation/ingestion or dermal contact.

- **Implementability –** Conventional excavation is readily implementable, and the equipment, attachments, and operators are widely available. The equipment can be readily adapted to the material and conditions at the site.
- **Cost –** Low to moderate depending on the volume requiring removal.

4.4.3.2.2 Unsaturated Soil Summary of the Removal Process Option

Conventional excavation equipment is carried forward as the representative process option for unsaturated soil removal because of its effective application for a wide range of wastes, its equipment availability, and its widespread use in environmental restoration activities.

4.4.3.3 In Situ Treatment

In situ treatment technologies provide varying levels of unsaturated soil treatment and reduce the mobility and/or toxicity of the contaminants associated with soil and present as DNAPL. The in situ treatment technologies under consideration are physical/chemical and biological treatments.

4.4.3.3.1 Physical/Chemical Treatment

MNA, air sparging/soil vapor extraction, in situ oxidation, thermal treatment, electrokinetics, and nanotechnology are process options considered potentially applicable to the soil at LHAAP-18/24.

Monitored Natural Attenuation. MNA is a remedial process option that will achieve the cleanup levels over time. Natural subsurface processes such as dilution, volatilization, biodegradation, adsorption, and chemical (abiotic) reactions with subsurface materials are responsible for reducing contaminant concentrations. The VOCs and perchlorate are amenable to MNA.

- **Effectiveness –** MNA is considered under CERCLA on a case-by-case basis. USEPA guidance has been developed to aid in the selection of this process option for VOCs. MNA has been selected for a number of CERCLA sites. MNA at this site while occurring has had limited effectiveness for unsaturated soil contaminants based on longevity of contaminants present in the unsaturated soil.
- **Implementability –** Sampling over time of impacted soil will need to be performed to determine effectiveness. Tools are available to conduct sampling and analysis of unsaturated soils.
- **Cost –** Low to moderate but could be high with specialty tests and if MNA takes a long time to achieve the RAOs.

Air Sparging/Soil Vapor Extraction. This process option is designed to remove VOCs from the unsaturated soils by volatilizing these contaminants through the introduction of air. Air is introduced into the soil, assisting in the volatilization of organics associated with the soil. Extraction points are installed into the vadose zone and a vacuum is drawn on these wells. The extraction system draws off VOCs from the soil vapor phase. The extracted chemicals are then

treated. This process can be used in those areas where VOCs exist in vadose zone soil that is relatively permeable.

- **Effectiveness –** This process is very effective on highly volatile contaminants (e.g., TCE) and highly permeable formations. It is incompatible with certain soil types, and high humic content inhibits volatilization of contaminants. Implementation at LHAAP-18/24 is complicated by the subsurface heterogeneity and high clay content soil that may limit the effectiveness of air sparging by retarding the movement of air and vapors through the soil column. The presence of discontinuous high-permeability zones can result in preferential air flow paths, limiting the effectiveness. Air sparging is not effective for remediating perchlorate or metals.
- **Implementability –** Vapor extraction and air sparge equipment is readily available and commercial vendors are available to design and operate these systems. This process has been used at many hazardous waste sites in relatively homogeneous media. Organics that are removed from the vapor extraction points require ex situ treatment. Site characterization and modeling are required to determine the proper location of the injection and extraction wells and extraction rates.
- **Cost –** Low to moderate.

In Situ Oxidation. Contaminated media are treated through the addition of oxidizers, such as potassium permanganate, hydrogen peroxide, activated persulfate, or ozone which convert the contaminants to a less mobile or toxic form. This process option is applicable to VOCs such as TCE.

- **Effectiveness –** In situ oxidation is effective on contaminants in a relatively homogeneous and porous medium. The shallow soil zone at LHAAP-18/24 is largely non-homogenous, of variable porosity, and discontinuous. Chemical oxidation is most effective for VOCs (particularly TCE) and is considered a suitable approach for the primary CoCs at LHAAP-18/24 (MC and TCE). Multiple applications might be required to treat a certain area. Precipitates formed during the oxidation process could decrease effective permeability and make the process less effective. Chemical oxidation is not effective for treatment of metals, perchlorate, or chlorinated alkanes such as 1,2- DCA.
- **Implementability –** This process option is readily implementable but requires addition of moisture to the vadose zone for soluble oxidants, which could result in mobilizing the CoCs to groundwater. An additional concern is related to distribution and exposure of the contaminants to the chemical agents exists. Another concern is the release of excess reactants or byproducts to the environment. There have been limited applications of these processes for vadose zone soils, which are generally more readily implemented in the ex situ mode. A recent USEPA evaluation by their Technology Innovation Office concluded that the application of in situ oxidation is highly dependent on the delivery system (USEPA, August 2006).
- **Cost –** Moderate.

Thermal Treatment. Heating the subsurface can effectively and quickly volatilize large quantities of VOCs, including those associated with the vadose soil. Available technologies include ERH, steam injection, and thermal conductive heating, which are typically coupled with

a soil vapor extraction system to capture VOCs. ERH is a complicated technology and is not cost effective on small volumes of soil. Steam injection and conductive heating involve the ex situ generation of heat and steam, which is delivered to the subsurface through new or existing vadose zone wells. VOCs are volatilized and carried to the soil vapor extraction system by steam. While thermal treatment to remediate limited vadose zone soil is not cost effective, use of this technology to treat vadose zone soil (e.g., under the UEP cap) could be readily extended if the technology is selected to treat saturated source areas.

- **Effectiveness –** Removal of TCE, MC, and other VOCs is anticipated to be effective using steam stripping. For shallow contamination (e.g., < 10-12 ft), capture of stripped VOCs may not be efficient due to the short distance to the ground surface. Thermal technology is not anticipated to have an effect on perchlorate (an ion) or metals.
- **Implementability –** A significant disadvantage to thermal treatment is that it may compromise the HDPE liner installed along the northern and western perimeters of the site, as well as the network of HDPE piping in the shallow soil (which carries groundwater to the treatment plant). Affected HDPE components could be replaced following thermal treatment, but replacement costs would be significant for the liner. Alternatively, the treatment could be operated at lower temperatures or operated away from the liner; both would lower overall effectiveness of the technology if certain target areas are not treated.
- **Cost –** For small volumes, the process is not cost competitive with respect to other remediation methods. General cost is high to very high.

Electrokinetics. Induced low voltage DC between the electrodes placed in the ground in an open flow arrangement causes water, ions, and colloids to migrate to the electrodes. Water moisture or introduced fluid would be the conductive medium. Movement occurs under induced potential via electroosmosis, electromigration, and electrophoresis. The advantages of electrokinetics is its effectiveness in fine-grained soils and for in situ treatment of heavy metals. Technology limitations include solubility of contaminants to be treated, corrosion of anode material, migration rates are slow, change in ambient pH could lead to precipitation and fouling of the cathode, and the presence of large quantities of iron or iron oxides can reduce removal efficiencies. Enhanced electrokinetics techniques attempt to reduce these limitations and improve process performance.

- **Effectiveness –** Removal of CoCs is anticipated to be effective for fine grained soil areas. Some volatilization of VOCs could occur. On its own, electrokinetics has severe limitations such as precipitation (fouling of) on electrodes, severe pH increase in soil, and solubility limitations of contaminants. Therefore, electrokinetics combined with other technologies (enhanced electrokinetics) would be required to minimize limitations and improve opportunity to mobilize contaminants for removal or in situ treatment (e.g., oxidation and bioremediation). This process may not be cost-competitive for small impacted areas and low concentrations that could be remediated by other methods such as excavation and disposal.
- **Implementability –** Prior to implementing full scale treatment, it may be appropriate to perform additional soil characterization to better define potential limiting factors. Treatability testing to ensure that the system design delivers as expected might be required. These pretreatment needs make the process more expensive and can be considered too cumbersome to treat a small volume of impacted soil.

- **Cost –** High.

Nanotechnology. Remediation of unsaturated soil using nanotechnology is not meaningful to implement in situ because distribution of nanoparticles in unsaturated soil is not effective. Soil excavation and above ground treatment is possible but the cost and effort for a small volume could exceed that for off-site disposal. Additionally, loss of VOCs would occur during excavation and treatment. Treatability testing to determine the dose and contact time would be required.

- **Effectiveness –** nZVI is proven to remove TCE, MC, and other chlorinated VOCs in groundwater and DNAPL source areas but it is not typically applied to unsaturated soil. Effectiveness depends on contact between contaminants and the iron particles and this might require excavating the soil. The process should be effective as long as contact is achieved between the chlorinated VOCs and iron.
- **Implementability –** Manufacturing nZVI and its variations such as EZVI and BNP is commercially available. Implementation can be conducted after excavating the soil.
- **Cost –** Medium to high depending on volume to be treated.

4.4.3.3.2 Biological Treatment

Biological treatment process options use living organisms such as bacteria or fungi to detoxify or immobilize contaminants in groundwater. These process options are primarily used to convert organic contaminants into nontoxic products.

Phytoremediation. This general process option covers a wide range of individual plant species to remove VOCs and metals from the subsurface via plant uptake and release to the environment.

- **Effectiveness –** Phytoremediation could be effective for shallow contamination. The rate of removal of VOCs or metals is slow but for low to medium concentrations, this process could be effective. The time for the trees to grow to suitable height (depth of root zone) might be too long. This process is not known to be effective for perchlorate. Application of phytoremediation at the site has been implemented but not monitored. Based on poor conditions of the trees within LHAAP-18/24 and the continued presence of high concentrations of contaminants in the soil and groundwater, phytoremediation does not appear to have been successful at this site.
- **Implementability –** Planting trees is a straightforward process.
- **Cost –** Low to moderate.

4.4.3.3.3 Summary of In Situ Treatment Process Options

There are numerous in situ soil treatment process options available. Significant reductions in VOC concentrations via MNA within the vadose zone are not known to be achievable at this site. MNA is not retained as a remediation option for unsaturated soils.

The effectiveness of air sparging/soil vapor extraction process option for treatment of vadose zone soil at LHAAP-18/24 may be limited by site heterogeneity (preferential transport pathways limits effectiveness) or contaminant characteristics (air sparging is not effective for perchlorate

and metals). Capture of vapors from soil vapor extraction for shallow soil may not be effective. This technology is not retained.

In situ chemical oxidation is not effective for vadose zone remediation because oxidation required wet conditions to be effective with the exception of ozone use. Addition of moisture may facilitate migration to groundwater. This process is not effective for perchlorate and metals. Therefore, in situ oxidation is not retained.

Thermal process options such ERH and electrokinetics are not cost effective for small volumes of soil and capture of vapors from the shallow soil may be difficult. ERH for treatment of soil under the UEP cap could be combined with DNAPL remediation. Steam stripping is applicable, but capture of vapor from shallow soil may be difficult. nZVI is unlikely to be applicable for in situ treatment of unsaturated soil.

Phytoremediation can be effective, but the process can be too slow to remove contaminants from the affected zone.

Only ERH of unsaturated soil under the UEP is retained.

4.4.3.4 Ex Situ Treatment

Ex situ treatment technologies provide treatment of excavated soils or extracted vapors on site. These technologies are applied to reduce the volume, mobility, or toxicity of recovered material. Although ex situ treatment technologies considered are physical/chemical, thermal, and biological, they have been grouped into one process option under an on-site treatment technology using a skid-mounted system near the extraction point.

4.4.3.4.1 On-Site Skid-mounted Treatment Plant

A skid-mounted or mobile treatment plant could be built near the point of soil excavation or vapor extraction. The treatment system would be designed for removal of the CoCs from the soil or vapors.

Thermal treatment methods such as thermal desorption or incineration can be effective for removal or oxidation of VOCs but the lack of availability, high cost, and complex processes associated with these methods to treat a limited amount of material is not feasible. Chemical oxidation methods could be effectively implemented to treat the excavated soil but vapor control is required. Additionally, the cost to design, procure, construct, and operate a chemical oxidation process for a limited volume of soil can be moderate to high. Chemical reduction using chemicals such ZVM is possible for excavated soil. Use of activated carbon and/or thermal oxidizer are established technologies for treatment of vapor phase VOCs.

- **Effectiveness –** A skid-mount system could be effective for chemical oxidation and chemical reduction of soil and thermal treatment and GAC for vapors.
- **Implementability –** The implementation of this option is difficult. A few studies would be needed to design the plant to meet site conditions. Equipment availability and vendor expertise in this area is limited. Application of a complex process for small volumes of soil is not feasible.

- **Cost –** High. The capital cost of this option is large relative to the estimated volumes of soil that could be generated.

4.4.3.4.2 Summary of Ex Situ Treatment Process Options

A new skid-mounted plant will not be retained for remedial alternative development. Off-site management of excavated soils provides a safer and more cost-effective approach.

4.4.3.5 Disposal

The disposal GRA consists of those technologies that provide for the disposal of removed wastes at new or existing, permitted disposal facilities. Both on-site and off-site facilities are evaluated. A selection of on-site facilities versus off-site facilities is made for developing alternatives.

4.4.3.5.1 Off-Site Disposal

Off-site disposal options for excavated soil include off-site treatment and disposal facilities, a RCRA disposal facility, or an industrial landfill. The selection of the disposal facility depends on the waste characteristics.

Treatment, Storage, and Disposal Facility. A TSD facility is a commercial, permitted, off-site facility that is licensed to treat, store, and/or dispose of a variety of waste streams. There are numerous such facilities all over the country offering broad ranges of treatment options, many of which could effectively treat and dispose of the LHAAP-18/24 waste and soil. This option would be used if treatment before disposal is needed.

- **Effectiveness –** A TSD facility is effective at treating and disposing of treated wastes in a permitted, off-site disposal facility.
- **Implementability –** Numerous facilities exist that have and are treating wastes similar to those found at LHAAP-18/24. These facilities are already permitted and licensed to operate. Wastes have to meet the waste acceptance criteria of the receiving TSD facility.
- **Cost –** Moderate.

RCRA Disposal Facility. This process option consists of any number of existing disposal facilities that use engineered features such as multilayer liners and caps, leachate detection and collection systems, run-on/-off controls, and intrusion barriers to isolate wastes from human and environmental receptors.

- **Effectiveness –** Disposal involves permanent disposition of the RCRA-generated contaminated soil in a manner that protects human health and the environment. Off-site disposal would include the transportation of excavated soils to an approved and licensed facility. This process option is not effective for extracted DNAPL.
- **Implementability –** Implementation is moderate if the waste acceptance criteria can be met.
- **Cost –** Moderate.

Industrial Landfill. An existing industrial landfill can be used to dispose of that debris or refuse that is not a RCRA waste or has been decontaminated to acceptable levels. Such a facility is a Class II lined facility permitted to receive industrial, commercial, institutional, land-clearing,

and construction/demolition waste. The facility does not accept RCRA-hazardous waste or free liquids. This option would be used to dispose of waste that is considered hazardous to human health and the environment but is not a RCRA-hazardous waste.

- **Effectiveness –** Industrial landfills are effective in isolating low hazard wastes from the environment and human receptors because the waste acceptance criteria severely restrict the type and concentrations of waste that may be disposed.
- **Implementability –** Disposal of the excavated clean wastes or treated wastes would involve transportation and compliance with waste acceptance criteria. An industrial landfill does not accept hazardous soil.
- **Cost –** Moderate.

4.4.3.5.2 On-Site Disposal

On-site consolidation is considered as the technology process option for on-site disposal.

Consolidation. Consolidation involves placing treated LHAAP-18/24 soil back into LHAAP areas. The waste is excavated, partially treated on the site if needed, and then placed elsewhere on LHAAP. The contaminants in the treated waste would have to have been destroyed or rendered immobile, making the treated waste better suited for placement. This option precludes the need to transport the treated waste to an off-site disposal facility. A single or multilayer cap would then be placed over the waste. If the waste is fully treated, no special disposal process option is needed.

- **Effectiveness –** Consolidation is effective in isolating the very low hazard wastes from human receptors and the environment. It can limit the area requiring long-term institutional controls.
- **Implementability –** Consolidation is used at other hazardous waste sites around the country where off-site disposal options are unavailable or undesirable and where the continued on-site presence of treated waste is not problematic. Given the potential future land uses at the LHAAP, there may be regulatory and public reluctance to moving the waste around the LHAAP.
- **Cost –** Low compared to off-site disposal.

4.4.3.5.3 Summary of Disposal Process Options

RCRA landfill, TSD, and industrial landfill off-site disposal process options are carried forward for additional consideration until waste streams and volumes are more clearly identified via additional delineation. The on-site disposal option of consolidation is not retained because of the potential regulatory and public concerns about leaving waste on the site after having already removed it, the potential future land uses, and the widespread availability of off-site treatment and disposal facilities.

4.4.3.6 Summary of Representative Process Options for Unsaturated Soil

The following representative GRAs, technologies or process options are retained:

- No action

- LUCs
- Containment by slurry wall with soil cover
- ERH for unsaturated soil underneath the UEP
- Removal and off-site disposal

Development of the remedial alternatives is included in **Section 5.0**.

General Response Action	Technology	Process Option	Description	Evaluation Comments
No Action	None	Not Applicable		Required for consideration
Land Use Control	Access Restrictions	Covenants	Restricts land use and zoning (no use of groundwater, no residential use	Potentially applicable
	Monitoring	Physical Surveillance	Inspection of engineered remedial actions and conduct maintenance to ensure proper operations of engineered controls including the UEP cap	Potentially applicable
		Long-Term Media Monitoring	Long-term groundwater monitoring used to determine effectiveness of remedial actions	Potentially applicable
Containment	Capping	Soil Cover	Clean soil placed over contaminated areas to reduce infiltration	Potentially applicable
		Asphalt Cap	Asphalt cap placed over contaminated areas to reduce infiltration	Complete prevention of infiltration is not desirable to maintain sustainable groundwater extraction
		Multilayer Cap	Multiple layers of soil, clay, membranes and other materials to prevent infiltration	Complete prevention of infiltration is not desirable to maintain sustainable groundwater extraction
	Lateral Containment	Slurry Wall	Soil/bentonite-filled trench to control or divert groundwater flow	Potentially applicable
		Ground Curtains	Chemical or cement-based grout injected in a series of overlapping columns to form a barrier to groundwater flow	No significant advantages over slurry wall and soil heterogeneity could result in uneven distribution of grout
		Sheep Pilings	A subsurface barrier to groundwater flow constructed by inserting overlapping steel panels into the ground	No significant advantages over slurry wall
	Hydraulic Containment*			
Removal	Groundwater Collection/ Removal	Vertical Extraction Wells	Groundwater extraction wells designed to remove contaminated groundwater	Potentially applicable; existing extraction wells at LHAAP - 18/24 perform satisfactorily
		Interception Trenches	Trench filled with permeable materials designed to intercept and collect shallow groundwater	Requires long-term maintenance; most existing trenches at LHAAP-18/24 perform satisfactorily
		Horizontal Wells	Wells installed horizontally beneath a waste area to collect groundwater and leachate	Considered inferior to trenches and vertical wells in previous studies at LHAAP-18/24
In Situ Treatment	Physical/ Chemical	Monitored Natural Attenuation	The monitored attenuation of contaminants through natural biological/chemical/physical processes	Potentially applicable to dilute dissolved phase
		Air Sparging/Soil Vapor Extraction	Air injected into saturated matrices to remove contaminants through volatilization	Interferes with anaerobic active natural processes; site heterogeneity reduces effectiveness
		In-situ Oxidation	Chemical oxidants or reducers added in situ to convert organics to less toxic forms	Potentially applicable to VOCs and 1,4-dioxane, not effective for perchlorate or metals; site heterogeneity reduces effectiveness of oxidant distribution in the subsurface
		Permeable Reactive Barrier	A trench filled with a reactive or sorbent material designed to treat groundwater as it passes through the trench	Requires a treatability study and long-term maintenance, applicable to dilute migrating plumes only; not effective for all COCs
		Electrokinetics	Application of a direct Current between electrodes inserted across a treatment area to allow migration and collection off contaminants on the electrodes for treatment or extraction	Slow process. Requires the use of a large number of electrodes; effective in heterogeneous formations. Additional studies would be required.
		Nanotechnology	Use of nZVI introduced to subsurface to convert chlorinated ethenes to less toxic forms	Non selective remediation method, suffers from site heterogeneity limiting uniform distribution into the subsurface; generally not effective for perchlorate and MC
	Thermal	Electrical Resistive Heating	Electricity delivered to the subsurface generates heat that volatilizes VOCs	Not applicable to large volumes of dilute groundwater; could damage subsurface piping, wells, and HDPE membranes. Could be used for localized high 1,4-dioxane concentration areas
		Steam Injection	Injected steam heats the subsurface to volatilize VOCs	Not applicable to large volumes of dilute groundwater; could damage subsurface piping, wells, and HDPE membranes
	Biological	Enhanced Bioremediation	Microbes and nutrients are injected into the subsurface to biologically degrade organics	Potentially applicable to both organics and perchlorate
		Phytoremediation	Plants are used to remove, stabilize, or destroy contaminants	Takes too long and process is slow; not effective for depth of contamination on site
Ex Situ Treatment	On Site Treatment	New Treatment Plant	Mobile or skid-mounted system installed near extraction points or to replace a portion of the existing GWTP	Requires design and treatability study; a new plant extends the longevity of the treatment process;
		Existing GWTP	Treatment processes at existing GWTP	Operating GWTP; potential new prcess for 1,4-dioxane treatment. Retained as an alternate should a new GWTP is not used
Disposal	On Site Disposal	Surface Water Discharge	Discharge of treated groundwater to surface water	These are current uses of effluent from the GWTP
		Reinjection	Injection of treated groundwater at LHAAP-18/24	Process discontinued at LHAAP - 18/24
		Irrigation	Watering ground cover vegetation at LHAAP-18/24 to maintain erosion control	These are current uses of effluent from the GWTP
		Release to INF Pond	Release of treated groundwater to the INF Pond	These are current uses of effluent from the GWTP

General Response Action	Technology	Process Option	Description	Evaluation Comments
No Action	None	Not Applicable		Required for considerations
Land Use Control	Access Restrictions	Covenants	Restricts land use and zoning (no use of groundwater, no residential use	Potentially applicable
	Monitoring	Physical Surveillance	Inspection of engineered remedial actions and conduct maintenance to ensure proper operations of engineered controls including the UEP cap	Potentially applicable
		Long-Term Media Monitoring	Long-term groundwater monitoring used to determine effectiveness of remedial actions	Potentially applicable
Containment	Capping	Soil Cover	Clean soil placed over contaminated areas to reduce infiltration	Potentially applicable
		Asphalt Cap	Asphalt placed over contaminated areas to reduce infiltration	Complete prevention of infiltration is not desirable to maintain sustainable groundwater extraction
		Multilayer Cap	Multiple layers of soil, clay, membrane, and other materials to prevent infiltration	Complete prevention of infiltration is not desirable to maintain sustainable groundwater extraction
	Lateral Containment	Slurry Walls	Soil/bentonite-filled trench to control or divert groundwater flow	Potentially applicable
		Ground Curtains	Chemical or cement-based grout injected in a series of overlapping columns to form a barrier to groundwater flow	No significant advantage over slurry wall and soil heterogeneity could result in an uneven distribution of grout
		Sheet Pilings	A subsurface barrier to groundwater flow constructed by inserting overlapping panels into the ground	No significant advantage over slurry wall
Removal	Excavation	Conventional Mechanical Excavation	Ordinary earthmoving equipment such as backhoes, loaders, and bulldozers	Complicated by depth of impacted soil and potential excess volume removed to reach deep soils
	DNAPL Extraction	Surfactant Flushing and Extraction	Injection of surfactant to mobilize DNAPL to extraction wells for surface management	Distribution of surfactant to impermeable zones may not be possible; reduces source and longevity of remediation
In Situ Treatment	Physical/ Chemical	Monitored Natural Attenuation	The monitored attenuation of contaminants through natural biological/chemical/physical processes	Not applicable due to high contaminant concentrations / DNAPL phase
		Air Sparging/Soil Vapor Extraction	Air injected into the saturated matrices to remove contaminants through volatilization	Not applicable due to high contaminant concentrations / DNAPL phase
		In-situ Oxidation	Chemical oxidants or reducers added in situ to convert organics to less toxic form	Other processes are more effective at reduction of sources / DNAPL; soil heterogeneity reduces effectiveness of oxidant distribution
		Permeable Reactive Barrier	A trench filled with a reactive or sorbent material designed to treat groundwater as it passes through the trench	Not applicable due to high contaminant concentrations / DNAPL phase; not applicable to immobile contaminants
		Electrokinetics	Application of a direct Current between electrodes inserted across a treatment area to allow migration and collection off contaminants on the electrodes for treatment or extraction	Slow process. Requires the use of a large number of electrodes; effective in heterogeneous formations. Additional studies would be required.
		Nanotechnology	Use of nZVI introduced to subsurface to convert chlorinated ethenes to less toxic forms	Non selective remediation method, suffers from site heterogeneity limiting uniform distribution into the subsurface; generally not effective for perchlorate and MC
	Thermal	Electrical Resistive Heating (ERH)	Electricity delivered to the subsurface generates heat that volatilizes VOCs	Potentially applicable to DNAPL; could damage subsurface piping, wells, and HDPE membranes
		Steam Injection	Injected steam heats the subsurface to volatilize VOCs	Potentially applicable to DNAPL; could damage subsurface piping, wells, and HDPE membranes
	Biological	Enhanced Bioremediation	Microbes and nutrients are injected into the subsurface to biologically degrade organics	Potentially applicable to both VOCs and perchlorate but high concentrations/DNAPL could be toxic; time frame might be too long
		Phytoremediation	Plants are used to remove, stabilize, or destroy contaminants	Takes too long and process is slow; too shallow for deep DNAPL areas
Ex Situ Treatment	On Site Treatment	New Treatment Plant	Mobile or skid-mounted system installed near extraction point	Difficult to implement and requires design and treatability but could be part of another remedy such as ERH
Disposal	Off Site Disposal	TSD	Contaminated media sent to an off-site facility for treatment and/or disposal	Potentially applicable, destination will depend on disposal test results
		RCRA Disposal Facility	RCRA hazardous waste disposal in an off-site RCRA Subtitle C facility	Potentially applicable, destination will depend on disposal test results
		Industrial Landfill	Nonhazardous waste disposal in an off-site RCRA Subtitle D Facility	Not applicable as saturated soils/DNAPL are likely hazardous
	On Site Disposal	RCRA Disposal Facility	RCRA hazardous waste disposed in an on-site RCRA Subtitle C Facility	On-site RCRA facility not available
		Consolidation	Consolidate waste with other waste	Difficult to implement due to regulatory and public resistance to dispose waste at LHAAP

	Thermal	Electrical Resistive Heating	Electricity delivered to the subsurface generates heat that volatilizes VOCs	Not cost effective on small soil volumes but soil beneath the UEP cap could be combined with DNAPL treatment areas near the UEP
		Steam Injection	Injected steam heats the subsurface to volatilize VOCs	Not effective for shallow contamination
	Biological	Phytoremediation	Plants are used to remove, stabilize, or destroy contaminants	Takes too long and the process slow
Ex Situ Treatment	On Site Treatment	New Treatment Plant	Mobile or skid-mounted system near extraction points	Difficult to implement and requires design and treatability
Disposal	Off Site Disposal	TSD	Contaminated media sent to an off-site facility for treatment and/or disposal	Potentially applicable; destination will depend on disposal test results
		RCRA Disposal Facility	RCRA hazardous waste disposal in an off-site RCRA Subtitle C facility	Potentially applicable; destination will depend on disposal test results
		Industrial Landfill	Nonhazardous waste disposal in an off-site RCRA Subtitle D Facility	Potentially applicable destination will depend on disposal test results
	On Site Disposal	RCRA Disposal Facility	RCRA hazardous waste disposed in an on-site RCRA Subtitle C Facility	On-site RCRA facility not available
		Consolidation	Consolidate waste with other waste	Difficult to implement due to regulatory and public resistance to dispose waste at LHAAP

Figure 4-3

Table 4-1: Identification and Screening of Remedial Action Technologies LHAAP-18/24

General Response Action Technology Type	Description and Process Options	Retained for Evaluation in Section 4.4?	Considerations
Groundwater			
No action	No remedial measures to be taken.	Yes	The “no action” alternative must be fully evaluated according to 40 CFR 300.68.
Land Use Control (LUC)*	Restrict future use of and access to the contaminated media to prevent unauthorized exposure to contaminated media. Monitoring is grouped with LUC because it identifies monitoring is necessary to establish the continued need for other LUC.	Yes	For contaminated groundwater, unsaturated soil, and DNAPL a number of controls are feasible approaches for preventing exposure.
Containment*	Containment isolates the groundwater plume, associated DNAPL zones, and unsaturated soils in place and prevents migration. Containment can be hydraulic or by means of a solid barrier. Hydraulic containment for groundwater is included under “Removal.” Solid barriers include: • Capping Systems • Lateral Containment systems	Yes	Barrier containment is potentially effective to isolate the high concentration regions of the groundwater plume (e.g., DNAPL regions) where effective treatment may be difficult.
Removal	Groundwater removal can serve two purposes: (1) hydraulically isolate the groundwater to prevent its migration off site or to surface water, and (2) remove dissolved contaminants with groundwater from the subsurface for subsequent treatment and/or disposal. Technologies include: • Extraction wells • Interceptor collection trenches	Yes	On-going extraction at LHAAP-18/24 has demonstrated that these technologies are applicable to the contaminants and the site conditions for groundwater.

Table 4-1: Identification and Screening of Remedial Action Technologies LHAAP-18/24

General Response Action Technology Type	Description and Process Options	Retained for Evaluation in Section 4.4?	Considerations
In Situ Treatment	Treat groundwater in place to reduce the contaminant mobility or toxicity. Includes: • Monitored Natural Attenuation • Air sparging/soil vapor extraction • Oxidation • Permeable reactive barriers • Bioremediation • Phytoremediation • Thermal treatment	Yes	These are generally proven technologies that are potentially applicable to the major contaminants found at LHAAP-18/24. Subsurface characteristics (heterogeneity and presence of contaminants within fine-grained soils) will make design and implementability difficult for some of these technologies associated with the ability to drive the applied chemicals into fine-grained soils where contaminants reside. Phytoremediation is not appropriate for the depths of contamination within the saturated zone and is not considered further for groundwater. Some of these technologies are not applicable to perchlorate or metals such as air sparging or chemical oxidation and require use of other technologies.
Ex Situ Treatment	Treat extracted groundwater or vapor after removal from the subsurface • On-site with mobile treatment (for groundwater and/or vapor), or • Existing Groundwater Treatment Plant with potential modification to treat 1,4-dioxane (for groundwater). Examples include advanced oxidation processes using hydrogen peroxide with ultraviolet light or ozone with hydrogen peroxide (HiPOx™). • New GWTP with advanced oxidation processes.	Yes	On-going treatment at the site demonstrates that ex situ treatment of groundwater is applicable. Air emission determination would be made to determine the level of vapor mitigation needed in association with vapor extraction.
Groundwater Disposal	Discharge of treated groundwater to surface water or to the site via a sprinkler system.	Yes	Discharge to Harrison Bayou and on-site irrigation have been practiced for the existing GWTP. These operations demonstrate that disposal is applicable for the contaminants and specific conditions at LHAAP-18/24.
Soil in Saturated Zone – Potential Secondary Source Areas (DNAPL)			
No action	No remedial measures to be taken.	Yes	The “no action” alternative must be fully evaluated according to 40 CFR 300.68.

Table 4-1: Identification and Screening of Remedial Action Technologies LHAAP-18/24

General Response Action Technology Type	Description and Process Options	Retained for Evaluation in Section 4.4?	Considerations
Removal	Removal of source soils from the subsurface for ex situ treatment or disposal. Includes: • Excavation of soil from the subsurface • Surfactant flushing and extraction of solubilized DNAPL	Yes	Excavation could be readily implemented at LHAAP-18/24, though excavation into the saturated zone will be problematic due to dewatering and the costs associated with shoring and/or sloping around the excavations. DNAPL surfactant flushing and subsequent extraction might be successful in reducing the mass of DNAPL in the subsurface but will be less effective in fine-grained soils.
In Situ Treatment	Treat saturated soil in place to reduce the contaminant mobility or toxicity. Includes: • Monitored Natural Attenuation • Air sparging/soil vapor extraction • Oxidation • Permeable reactive barriers • Thermal treatment • Surfactant flushing • Bioremediation • Phytoremediation	Yes	These are generally proven technologies that are potentially applicable to the major contaminants found at LHAAP-18/24. Subsurface characteristics (heterogeneity and presence of contaminants within fine-grained soils) will make design and implementability difficult for some of these technologies associated with the ability to drive the applied chemicals into fine-grained soils where contaminants reside. Phytoremediation is not appropriate for the depths of contamination within the saturated zone and is not considered further for DNAPL. Surfactant flushing is discussed in removal process option.
Ex Situ Treatment	Treat soil/DNAPL after removal to reduce contaminant concentrations. • On-site with mobile treatment	No	Ex situ treatment of excavated soil or extracted DNAPL would be implemented only if it could be shown to be more cost effective than simply managing/disposing off site. This would only be true for very large volumes of soil, in which case soil removal itself would become prohibitively expensive.
Soil/DNAPL Disposal	Either dispose of excavated DNAPL soils or DNAPL if extracted via surfactants for example in RCRA Subtitle D landfill as nonhazardous (after off-site treatment) or Subtitle C landfill as hazardous waste depending on its characteristics.	Yes	This is a straightforward technology that can readily be implemented for the contaminants found at LHAAP-18/24. However, increasing volume can result in exorbitant costs or unacceptable truck traffic in the local area. Dewatering the soil before hauling off site would be required. The water might contain high concentrations of CoCs requiring treatment. Disposal off-site entails treatment such incineration before landfilling to achieve land ban standards.

Table 4-1: Identification and Screening of Remedial Action Technologies LHAAP-18/24

General Response Action Technology Type	Description and Process Options	Retained for Evaluation in Section 4.4?	Considerations
Unsaturated Soil			
No action	No remedial measures to be taken.	Yes	The “no action” alternative must be fully evaluated according to 40 CFR 300.68.
Removal	Unsaturated soil removal removes soil for subsequent treatment and/or disposal. Technologies include direct excavation of the unsaturated soil.	Yes	Soil excavation is a well-established technology applicable at the site.
In Situ Treatment	In-situ treatment for unsaturated soil entails technologies such as: • Monitored Natural Attenuation • Air sparging/soil vapor extraction • Oxidation • Phytoremediation • Thermal treatment	Yes	These are generally proven technologies that are potentially applicable to the major contaminants found at LHAAP-18/24. Subsurface characteristics (heterogeneity and presence of contaminants within fine-grained soils) will make design and implementability difficult for some of these technologies associated with the ability to drive the applied chemicals into fine-grained soils where contaminants reside.
Ex Situ Treatment	Treat excavated unsaturated soil or vapor after removal from the subsurface On-site with mobile treatment for vapors: • Thermal oxidizer • Activated carbon On-site with mobile treatment for soils: • Thermal treatment • Chemical oxidation • Chemical dechlorination	Yes	May not be cost-effective for small volumes of unsaturated soils (versus off-site disposal if excavated or release of vapors to the atmosphere under TCEQ remediation permit-by-rule concept)
Soil Disposal	Dispose of contaminated soil in RCRA Subtitle D landfill as nonhazardous waste.	Yes	This is a straightforward technology that can readily be implemented for the contaminants found at LHAAP-18/24.

5 DEVELOPMENT AND DESCRIPTION OF ALTERNATIVES

Section 5.1 presents the development of a range of alternatives based on the key assumptions regarding site and contaminant conditions **(Section 2.0)**, the RAOs and applicable ARARs **(Section 3.0)**, and the representative process options **(Section 4.0)**. **Section 5.2** presents the detailed description of the alternatives.

5.1 Development of Alternatives

5.1.1 Requirements and Preferences

The CERCLA process, as defined in the NCP, develops a remedy that protects human health and the environment, complies with ARARs (unless a statutory waiver is justified and granted), is cost-effective, and uses permanent solutions and alternative treatment or resource recovery technologies to the maximum extent practicable. A statutory preference for remedies that would result in permanent and significant decreases in toxicity, mobility, or volume through treatment and provide long-term protection is stated in Section 121 of CERCLA, as amended.

The NCP defines the following preferences in developing remedial action alternatives:

- Use of treatment to address the "principal threats" posed by a site, wherever practical.
- Use of engineering controls, such as containment, for waste that poses a relatively low, long-term threat and for which treatment is not practical.
- Implementation of a combination of actions, as appropriate, to achieve protection of human health and the environment. For example, in appropriate site situations, treatment of principal threats would be combined with engineering controls, such as containment, and LUCs for treatment residuals and untreated waste.
- Use of LUCs, such as drinking water supply controls and covenants, to supplement engineering controls for short- and long-term management to prevent or limit exposures to hazardous substances.
- Selection of an innovative technology when the technology offers the following: the potential for comparable or better treatment performance or implementability, fewer or lesser magnitude adverse impacts than other technologies, or lower costs than demonstrated technologies for similar levels of performance.
- Groundwater is expected to be returned to beneficial uses, whenever practicable, given the particular circumstances of the site. When such restoration is not practicable, the prevention of further migration of the plume and of exposure to the contaminated groundwater is expected.

These statutory requirements and preferences were given due consideration in the development of alternatives for LHAAP-18/24.

5.1.2 Development using Remediation Strategies and Process Options

The medium at LHAAP-18/24 presenting an unacceptable risk or hazard is groundwater in the shallow zone. Additional assessment at the site identified the presence of potential source areas

within the saturated soil (i.e., DNAPL zones) and unsaturated soil that could be a potential source to groundwater, in addition to the presence of unacceptable levels of CoCs in the upper Wilcox Formation. Thus, the purpose of the remedial alternatives is to present the decision maker with technical and economic options for remediation of groundwater and potential source areas at LHAAP-18/24. Although all of the action alternatives developed within this FS have been designed to achieve the RAOs and the statutory requirements under CERCLA, each alternative must also be sufficiently unique in its strategy and approach that the range of alternatives represents a reasonable spectrum of final site conditions in the view of the decision makers.

The process options that remain after screening were grouped and combined into alternatives to meet the RAOs as indicated on **Table 5-1**.

A number of process options are common to all action alternatives (Alternatives 2 through 6):

- Maintenance of the existing RCRA closure cap over the former UEP.
- MNA that occurs at the site to reduce and control CoC concentrations in areas outside the direct influence of the containment area. MNA was evaluated (**Appendix A**) and is a viable option for those areas but not as a primary remedy as additional evidence is needed for MNA to be used as a primary remedy. MNA for 1,4-dioxane has not been established at this time.
- Long-term LUCs to restrict groundwater use. The proposed remedy for each of the action alternatives necessitates that groundwater LUCs be maintained until CoC levels in soil and groundwater allow for unrestricted use and limited exposure. The LUCs include access restrictions and monitoring as discussed in **Section 4.4.1.2**.
- Operation of the existing GWTP and associated groundwater extraction system. The intensity and duration of continued use varies within the alternatives.

5.2 Description of Remedial Alternatives

The following sections describe the remedial alternatives in more detail (see **Table 5-1** for a presentation of the process options within each alternative). The details included in the alternative descriptions (e.g., quantities and dimensions) support the evaluation in **Section 6.0** and the cost estimates in **Appendix D**. Quantities and dimensions are provided for cost estimating purposes only and may be changed based on the design and additional field assessments. The process options are considered representative, and process options other than those considered here may be substituted once the decision on remedial approach is made.

5.2.1 Alternative 1 – No Action Alternative

As required by the NCP, the “no action” alternative provides a comparative baseline against which the action alternatives can be evaluated. Under this alternative, the groundwater extraction and treatment system would be shut down, and unsaturated soil, groundwater, and source areas would be left “as is” without implementing any additional containment, removal, treatment, or other mitigating actions. No other actions would be implemented to reduce potential future impacts to human health and the environment.

5.2.2 Alternative 2 –Enhanced Groundwater Extraction Inside Containment and Ex Situ Treatment, LUC, Enhanced ISB Inside & Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal

The goals for this alternative are to prevent exposure of the hypothetical future maintenance worker to contaminated groundwater at LHAAP-18/24, to prevent migration of contaminated groundwater to Harrison Bayou, to eliminate source soils from potential leaching to groundwater, to reduce saturated soil secondary source (DNAPL) from leaching to groundwater, and to ultimately return the groundwater to beneficial use.

The groundwater extraction system would continue to operate with additional ICTs inside the containment area brought back on line (i.e., modifications implemented as part of the pilot study implemented in 2008 (Shaw) will be partially reversed), and a new GWTP replacing the existing GWTP would be designed and used to treat extracted groundwater. **Figure 5-1** presents the existing GWTP process. Historically, ICTs 1, 3, 5, 6, 9, and 10 recovered groundwater impacted with perchlorate, TCE, and MC concentrations as shown in the table below:

ICT	Date	Flow Rate (gallons per month)	MC (µg/L)	MC Mass (lbs/day)	TCE (µg/L)	TCE Mass (lbs/day)	Perchlorate (µg/L)	Perchlorate (lbs/day)
1	4/12/2006	179	40	2E-06	2,600	1.3E-04	1,700	8.5E-05
3	4/12/2006	40,311	33,000	0.37	40,000	0.45	45,000	0.50
5	4/12/2006	4,482	53	6.6E-05	5	6.2E-06	4,400	5.5E-03
6	4/12/2006	4,755	100	1.3E-04	260	3.4E-04	3,100	4.1E-03
9	4/12/2006	54,360	150,000	2.27	24,000	0.36	16,000	0.24
10	4/12/2006	0	200	0	7,200	0	57,000	0

µg/L – micrograms per liter
gallons per month – gallons per month
lbs/day – pounds per day

These preliminary results indicate that certain ICTs that were turned off could be very productive in removing contaminant mass from the subsurface if the extraction flow rate is sustainable. Two ICTs (ICT 3 and ICT 9) in particular have a high potential for removing a large amount of CoC mass from the groundwater at least based on historical results. Sampling of the various inactive ICTs to determine which ICTs would be most effective will be conducted before determining which two ICTs will be activated. Therefore, as part of enhancement of contaminant mass removal from the subsurface, ICT 3 and ICT 9 will be retrofitted to become extraction trenches as part of this and other active FS alternatives.

Under this alternative, vertical extraction wells will be placed inside the residual DNAPL areas and connected to the extraction manifold to the GWTP. The purpose of these extraction wells is to enhance removal of DNAPL. Free DNAPL, if present, will be removed by the gradient created by the extraction wells if present within the zone of influence. Additionally, a large portion of trapped DNAPL will be removed by enhanced dissolution as fresh groundwater is forced through the zone of influence of the wells. While this extraction approach enhances DNAPL removal, it is not expected that residual DNAPL be completely removed within 30 years because hydraulic extraction methods are ineffective on low K zones. If extraction wells within the DNAPL areas

removed residual DNAPL, it is estimated that the DNAPL will be completely dissolved by the time it reaches the GWTP as the DNAPL droplets mix with pumped groundwater in a turbulent pumping regime. The presence of DNAPL in the ACD area may extend farther to the north toward ICT-12E and monitoring well 120, increasing the area to be treated for DNAPL. Therefore, the cost estimate for the DNAPL area in the vicinity of the ACD may become larger and will be considered during the remedial design phase.

Under this alternative, groundwater extraction acts to remove source mass and contain the contamination within the Shallow Zone only. Treated effluent from the plant would be released to Harrison Bayou or used as irrigation water.

The closure cap over the UEP will be maintained in good condition, preventing erosion and maintaining vegetative cover to reduce infiltration in this area and prevent any contamination present in the unsaturated soil beneath the UEP from migrating to groundwater. Removal of the impacted unsaturated soil beneath the UEP in the vicinity of 18CPT21 and 18CPT25 is discussed in this alternative including development of cost estimates but implementation might be deferred to a future date.

LTM would be conducted to confirm that contaminant concentrations are being reduced to acceptable levels over time. Long-term groundwater LUCs would be required for LHAAP-18/24 until cleanup levels are met for the groundwater CoCs. While groundwater extraction removes source mass, the rate of removal is limited by the rate of dissolution of CoCs from the soil and/or DNAPL areas.

Samples would be collected from groundwater monitoring wells, the treatment plant influent and effluent, and additional locations as necessary to document removal of CoCs within and outside the containment area. While there is no current or projected exposure to the groundwater, protective LUCs would be established and maintained to prohibit use of groundwater, restrict land use to non-residential, and maintain the UEP cap.

The estimated restoration time frame for this alternative is expected to exceed the conservative estimate presented in **Table 2-14** of 200 years. For Alternative 2, it is expected that the extraction and treatment system will continue to operate indefinitely to extract the soluble, adsorbed, and particularly DNAPL mass from within the containment, although enhanced ISB will be implemented that would reduce the overall lifecycle for the restoration of groundwater. At some time in the future, the extraction and treatment system might be turned off to allow MNA to take over when the magnitude of the contaminant plume becomes stable or shrinking.

In this alternative enhancement of biodegradation will be implemented in the shallow zone and Wilcox Formation to destroy contaminant mass. Chlorinated VOCs and perchlorate are susceptible to enhanced ISB, particularly within the plume areas where the contaminants have migrated with groundwater compared to source areas where contaminants were released. At this time, enhanced ISB for 1,4-dioxane is not considered a feasible approach but MNA for 1,4-dioxane will be evaluated as more data are collected.

Enhanced in situ treatment would consist of the application of bioremediation amendments along the outside southwestern boundary, southern area outside containment, near 18CPTMW23, AWD-4 to the northwest, and along the area outside the northeastern boundary. These are the areas with highest perchlorate and TCE concentrations outside the containment. Inside the containment, enhanced ISB would be conducted upgradient of MW-21 and 109 in the northeast

boundary, near monitoring wells 120, and in the area of MW-23 and location 18CPT03 where high perchlorate concentrations were detected. Enhanced bioremediation will also be practiced near 18CPTMW08SW, MW-14, and 18CPTMW22SW into the Wilcox Formation due to the presence of high concentrations of perchlorate in the Wilcox Formation in this area of the site. Bioremediation amendments would be injected using direct push tools in a linear fashion. Destroying MC, TCE, and perchlorate in situ, would result in rapid attenuation of CoCs within the area of influence of the proposed enhanced ISB areas. **Figure 5-2** shows the areas targeted for in situ treatment. For cost estimating purposes, two applications of in situ treatment amendments are assumed but additional applications will be implemented if deemed necessary by the monitoring results.

Removal of unsaturated soil containing CoCs at concentrations that could be a continuing source to groundwater will eliminate this potential transport pathway. Contaminated soil has been identified in four (4) areas totaling an area of approximately 7,000 ft^2 and an in-place volume of approximately 1,350 cubic yards.

Removal of targeted source soil is limited to the area of 18SB03 and 8A-911 from a depth of 8 ft to a depth of 12 ft bgs, and the area of 8A-972 between 5.5 and 12 ft bgs. The estimated extent of excavation in the area of 18SB03 and 8A-911 conducted in 1996 is 40 ft by 70 ft for a total area of 2,800 ft^2 and potential total volume of 11,200 ft3 or 414 yd^3. The estimated extent of excavation in the area of 8A-972 conducted in 1996 is 50 ft by 50 ft for a total area of 2,500 ft^2 and potential total volume of 16,250 ft3 or 602 yd^3. Soil in this area was excavated to a depth of 4 feet in 1996, and replaced with clean backfill. Therefore, this soil will be removed and stockpiled for reuse as backfill. However, before any soil excavation is done, targeted extent delineation will be conducted to confirm the extent of CoC impacts before excavation of soil is conducted. The excavated source soil will be disposed off-site after characterization. Removal of contaminated soil under the UEP may be performed as a contingent remedy in the future, if conditions change such that it poses an imminent threat to human health or the environment. Currently however, the existing cap effectively prevents human contact with contaminated soil, and minimizes infiltration of precipitation/runoff that could potentially mobilize COCs in the waste and impact shallow groundwater. The cap is regularly maintained and inspected to ensure its continuing effectiveness. If in the future, groundwater monitoring detects a significant increase in COC concentrations in wells downgradient of the UEP, and/or the water table elevation rises significantly, causing a large part of the underlying waste to become saturated, a detailed evaluation would be performed to assess the need for a contingent remedy, either for the soil or for the groundwater. The RD will address the triggering criteria for evaluating whether a contingent remedy is needed. The estimated volume is 11,400 yd^3 at a depth between 15 and 25 ft bgs below the top of the UEP cover. For this work to take place, a portion of the UEP cover will be removed and then restored after removal of impacted soil and backfilling.

5.2.2.1 Enhanced Hydraulic Control and Groundwater Treatment

The existing groundwater extraction system currently removes water from 21 interception trenches and two vertical extraction wells (EW-1 and 18WW17). This groundwater extraction hydraulically controls migration of contaminants. The extracted groundwater is pumped to the GWTP, stored in an equalization tank for batch treatment, sent through precipitation to remove metals, subjected to air stripping to remove VOCs, and treated in a biological reactor to remove

perchlorate. **Figure 5-1** presents this existing GWTP process. The treated effluent is no longer reinjected at two former interception trenches (ICT-6 and ICT-9) as of July 2012, rather the treated water is discharged to Harrison Bayou or released to the Burning Ground No. 3 via a sprinkler system. Five other interception trenches that were previously used to extract groundwater (ICT-1, ICT-3, ICT-5, ICT-10, and ICT-12A) were deactivated on February 18, 2008 as part of pilot test to encourage subsurface flow across the most contaminated portions of LHAAP-18/24. On December 5, 2012, ICT-12A was restored and is currently extracting groundwater.

To enhance recovery of CoCs from the shallow groundwater, ICT-3 and ICT-9 will be reestablished as extraction trenches. No new extraction will be implemented outside the formation because enhanced ISB will be undertaken as discussed below.

The time required by the extraction system to remove the mass of contaminants at LHAAP-18/24 from within the containment area by hydraulic control only (excluding the effect of enhanced ISB) can be considered in two parts. The accessible mass of contaminants dissolved in groundwater or adsorbed onto soil, and the source mass of contaminants present as DNAPL or residual contamination. The time to remove the estimated accessible mass of contaminants from within the containment area ranges from 1.5 years for MC to 8 years for TCE. However, the actual length of time is much longer due to diffusion limitations that control the removal rate of adsorbed CoCs especially from lower K zones, sorption retardation and transport time. These processes could make the remedial action duration an order of magnitude longer than estimated above. Soil partitioning retardation could increase the duration by 20% up to 10 fold. The time to remove source mass contaminants ranges from 110 years for MC up to 196 years for TCE. The actual time is much longer due to dissolution limitation of CoCs from DNAPL, assuming no DNAPL will be removed as a separate phase. These determinations were made in **Section 2.4.2.2** and presented in **Table 2-14**. These estimates are based on mass removal rates in 2015 and 2016 at LHAAP-18/24, assumed quantities of source mass, and assumed absence of retardation effects. Actual source masses may be less or more than estimated, resulting in shorter or longer time frames. Removal rates may tail off, resulting in longer time frames.

Based on these estimates, it is expected that the GWTP will be operated for a minimum of 30 years. The current GWTP is nearly 17 years old and is aging requiring frequent maintenance with anticipated more maintenance requirements with recapitalization for major item replacement in the near future. Additionally, the existing GWTP is oversized with a design capacity of up to 300 gpm while current operations recover an average flow of 20 gpm. The plant is currently operated one day per week and idling the remainder of the week with the exception of the FBR which operates continuously. Idling of the plant results in stagnant conditions creating additional maintenance problems associated with corrosion of equipment, deposition of precipitates in tanks, piping, pumps, valves, etc., and freeze stresses in the winter that could be avoided if operations were continuous. Due to the age of the plant, frequent maintenance requirements, and idling conditions, capitalization of a smaller foot print GWTP to replace the existing plant is used to develop remedial alternatives.

The new GWTP will be designed for a 50 gpm flow rate, which should accommodate the anticipated increase in groundwater extraction rates (reactivation of two ICTs and additional extraction wells in the DNAPL areas in addition to any extraction from LHAAP-17 that could go on line for a duration of 18 months). The system will consist of the same processes of metals

precipitation, VOC stripper, and FBR for removal of perchlorate. Without replacement of TK-140 (equalization tank) and TK-630 (effluent storage tank), and without a new belt press, the cost to recapitalize the GWTP is estimated at $2.8 million with an annual operational and maintenance cost of $513,000. No major replacement is anticipated for the first 10 years with 10% of the capital cost spent once every five years thereafter for major equipment replacement. Should treatment for 1,4-dioxane be required, an advanced oxidation process using the HiPOx™ technology consisting of hydrogen peroxide with ozone will be implemented. The estimated capital cost including equipment cost, piping/valves, site work, installation, engineering, and contingency is $500,000. The annual operating cost including replacement parts, labor, analytical, chemical cost, and power is estimated at $30,000 per year.

5.2.2.2 UEP Cap Maintenance

The former UEP was closed under RCRA in 1986 and capped by 1987. The UEP cap design consisted of removing the sludge, filling the UEP with common fill, covering the common fill with 4 ft of compacted clay, then applying 1 foot of sand, covered by 1 foot of topsoil. The surface of the cap has an average slope of three percent on top while the sides have a vertical to horizontal ratio of 1:4. It is graded and equipped with a sand drainage layer to promote sheet flow runoff to minimize erosion.

This cap would continue to be monitored, maintained, and repaired, as necessary, to ensure long-term effectiveness. This includes inspections of the cap to check for erosion, settlement, and deep-rooted vegetation, and implementation of necessary repairs. Routine maintenance and repair of the cap would include actions needed to ensure that the integrity of the cap is maintained (e.g., mowing, seeding, and settlement/erosion repair).

The importance of maintaining the cap is to prevent contaminants present in the unsaturated soil from leaching to groundwater. Three locations within the UEP identified the presence of contaminants within the unsaturated zone above the water table (18CPT21, 18CPT25, and 18CPTUEP05). The highest contamination was reported in 18CPT21. This area is included in the DNAPL impact zone that will be addressed under this alternative via hydraulic removal/containment of DNAPL. However, the other two locations are outside the DNAPL zone. Nonetheless, the presence of the cap provides a significant protection of this soil as long as cap maintenance continues to minimize infiltration of rain water.

5.2.2.3 Land Use Control

The LUCs would be implemented to prevent any use of groundwater (other than monitoring) in both the shallow and Wilcox groundwater zones. This restriction would need to remain in place until CoC concentrations in soil and groundwater allow for unrestricted use and unlimited exposure.

5.2.2.4 Enhanced ISB

ISB would consist of the application of organic substrate (e.g., emulsified vegetable oil (EVO) or other formulations) as a bacterial food source, and a bacterial inoculation mix (e.g., SDC-9 or KB-1 Plus®), in areas of the groundwater plume outside the containment area within areas of high perchlorate and high TCE in the northeast, southwest, and southeast. Inside the containment, enhanced ISB would be conducted upgradient of MW-21 and 109 in the northeast

boundary, near monitoring wells 120 and MW-14, and in the area of MW-23 and location 18CPT03 where high perchlorate concentrations were detected. Enhanced bioremediation will also be applied near 18CPTMW08SW and 18CPTMW22SW into the Wilcox Formation due to the presence of high concentrations of perchlorate in the Wilcox Formation in this area of the site.

ISB would be applied using DPT injections. Injection via deep boreholes that are surface cased may be required for the Wilcox Formation. In the northeast boundary where no liners are present with the ICTs, ISB would be applied no closer than 100 foot from the site boundary so that extraction may continue to remove contaminant mass and to avoid extraction of injected ISB amendments. Tracer tests will be conducted to determine whether the proposed injection locations are within or outside the capture zone of the extraction system with the goal to prevent injected substrate from being pulled into the extraction ICTs. Additionally, in order to minimize loss of ISB amendments, extraction wells would be temporarily shut down when ISB treatment amendment begins to appear in the wells. If ISB amendments reached extraction sumps this may result in biofouling problems that subsequently lead to groundwater extraction complications. Therefore, nearby ICTs and monitoring wells will be monitored for the occurrence of treatment amendments during implementation of enhanced ISB.

ISB in the Wilcox aquifer in the vicinity of 18CPTMW08SW would be applied using DPT injections without use of surface casing because in this area of the site within the shallow zone, MC is non-detect, TCE is approximately 45 µg/L, and perchlorate is 31,300 µg/L, which is lower than the perchlorate concentration in the Wilcox Formation at 35,000 µg/L (June 2016). Because injection will occur in the Wilcox aquifer, the ICTs will continue operations without interruption. ISB will enhance biodegradation of perchlorate in situ that would ultimately reduce the concentration of perchlorate and VOCs to a level that would allow NA to take over and reduce concentrations to below the cleanup levels. **Figure 5-2** shows the area targeted for ISB treatment based on existing information.

ISB amendments that result in creating geochemical changes (reducing conditions) favorable for anaerobic biodegradation could also have the potential result in mobilization of arsenic to groundwater. Under anaerobic reducing conditions, immobilized ferric iron becomes reduced and mobile in the form of ferrous iron. Arsenic generally co-precipitates with ferric iron and as the iron is solubilized in the form of ferrous iron, arsenic tends to come off the soil matrix into solution. Therefore, monitoring for arsenic in groundwater will be an integral part of this process.

ISB will enhance biodegradation of MC, TCE, and perchlorate in situ and ultimately reduce the concentrations of those chemicals to a level that would allow NA to take over and reduce contaminant levels to below the cleanup levels. **Figure 5-2** shows the multiple areas targeted for ISB treatment based on existing information.

For cost estimating purposes, the ISB is assumed to be implemented using a biobarrier injection configuration. The spacing of injection points is assumed to be 20 ft. Five ISB biobarriers are planned one in the northeast (900 ft), one in the southwest (600 ft), two 300-foot biobarriers in the northwest in the vicinity of 18CPTMW23 and 18CPTMW15 and AWD-4, 150 ft ISB in the vicinity of monitoring well 120, and one in the south (200 ft) for a total length of 2,450 ft and 122 DPT injection point. For the two grid areas, each grid is 200 ft by 200 ft in area and the

injection points are 25 ft apart for a total of 81 injection points in each grid. In the Wilcox aquifer, the ISB is assumed to use a biobarrier injection in two rows each 100 ft long and 50 ft apart. Injection will occur upgradient of 18CPTMW08SW based on potentiometric surface for the Wilcox Formation in this area of the site. Another 200 ft ISB will be used in the vicinity of 18CPTMW22SW and 150 ft ISB for MW-14.

Two applications of ISB treatment are assumed. The first application will be DPT injection of a slow releasing organic substrate (EVO) during year 1 in the areas depicted on **Figure 5-2**. Bioaugmentation is anticipated to be conducted 3 months after establishment of sustainable anaerobic conditions. It is assumed the first injection will reduce perchlorate concentrations by 90% and TCE and MC concentrations by 75%. The second application will be DPT injections of EVO and bioaugmentation during year 3 in same areas. It is assumed the second injection will reduce perchlorate by 90% and TCE and MC by an additional 75%. After the first 2 injections, it is assumed that MNA will control any remaining dissolved CoCs. However, evaluation of whether additional applications would be required will be made from performance data.

5.2.2.5 Unsaturated Soil Excavation and Off-site Disposal

Soil to the south of UEP (**Figure 5-2**) identified by TCE and MC exceedances in borings 18SB03 and 8A-911 between the depths of 8 and 12 ft bgs and boring 8A-972 between the depths of 5.5 and 12 ft bgs will be excavated. Additionally, soil in the former burn pit area to the west of the former UEP in borings 18CPTBB02 and 8A-940 between the depth of 4 to 10 ft bgs and boring 18SB04 between the depth of 10 and 14 ft bgs will be excavated. The shallow soil will be removed and stockpiled for use as backfill if clean. However, the backfill soil will be characterized before reuse. Excavation side walls and bottom will be sampled to confirm clean soil before backfilling with clean soil. Additional excavation will be conducted if contaminants are detected in the excavation walls or bottom. The contaminated soil will be stockpiled, sampled for characterization, and then hauled off-site for disposal at either a RCRA Subtitle C or Subtitle D landfill depending on soil characteristics. The samples will be analyzed for VOCs, metals, and perchlorate and any other criteria for disposal. It is assumed that 60 samples in all will be collected from the excavation area, removed soil, and backfill soil. The in-place volume is estimated at 1,350 yd^3 with an equivalent backfill borrow soil. The soil is assumed to be characterized as hazardous for TCE for costing purposes.

Two locations under the UEP were identified with high TCE an MC in the unsaturated soil. This soil will be excavated by removing the clean top soil to a depth of 15 ft below top of UEP then removing the impacted soil to a depth of 25 ft below the top of the UEP (approximately 18 ft bgs). The contaminated soil will be stockpiled, sampled for characterization, and then hauled off-site for disposal at either a RCRA Subtitle C or Subtitle D landfill depending on soil characteristics. The samples will be analyzed for VOCs, metals, and perchlorate and any other criteria for disposal. It is assumed that up to 200 samples will be collected from the excavation area, removed soil, and backfill soil. The in-place volume is estimated at 11,400 yd^3 with an equivalent backfill borrow soil. The soil is assumed to be characterized as hazardous for TCE for costing purposes. Once confirmation samples indicate clean bottom soil, clean borrow fill will be used to reconstruct the site topography. The top six feet will be made of a similar material as the UEP cap (4 ft of compacted clay, 1 ft of sand, 1 ft of top soil). The cost estimate for removal of

the soil underneath the UEP is included in this FS but the remedial action, if implemented, would not occur until 2024 at the earliest.

The excavation will be conducted using typical construction equipment such as a backhoe, bulldozer, front end loader, and haul trucks. Any stockpiles will be placed on plastic sheeting and will be covered until removed. Wetting of excavation areas to minimize dust generation will be conducted. Use of PPE and conducting air monitoring as needed for particulates will be implemented to protect the workers. Approximately 100 cubic yards per day are expected to be excavated. Operation will occur in Level D with air monitoring for particulates with optional upgrade to Level C for respiratory protection.

5.2.2.6 Groundwater Monitoring and MNA

MNA under this alternative is limited to CoCs present in the Wilcox Formation and areas in the shallow zone not influenced by either extraction or enhanced ISB. Data collected from the Wilcox Formation indicated the presence of high concentration of perchlorate in 18CPTMW08SW at a concentration of 35,000 µg/L, this area will be treated with enhanced ISB. Other areas within the Wilcox Formation targeted for remediation are MW-14 and 18CPTMW22SW. The remainder of the areas has low concentrations of perchlorate, TCE, and MC as presented in the Updated PSI Report Addendum (AECOM, 2016a) and Supplemental to the Updated PSI Report (AECOM, 2016c) such that NA mechanisms are meaningful for those areas. For example, the highest perchlorate concentration in the Wilcox Formation outside of the treatment areas is 672 µg/L at 18CPTMW08DW, the highest TCE concentration is 46.5 µg/L in 18CPTMW01SW, and the highest MC concentration is 746 µg/L in 18CPTMW01SW. Remediation of the Wilcox formation at this location is not recommended under this alternative due to the presence of high concentrations of TCE and MC in the shallow zone in this area of the site which under this alternative (extraction of groundwater within the UEP DNAPL area) will remain for a long time and could continue acting as a source to Wilcox Formation groundwater.

Available data for the Wilcox Formation wells are limited to between two and six data points for each of the wells installed in the spring of 2013, Spring of 2014, and Spring of 2016. Therefore, analysis of MNA in these wells is not possible at this time, but will be included in future assessments. Nonetheless, for this alternative, MNA is assumed to occur in the Wilcox Formation as was observed for low contaminated shallow zone wells (e.g., 18WW08 for perchlorate and MW-8 for TCE – **Appendix A**).

Natural attenuation analysis as presented in **Appendix A** indicated the occurrence of NA but in a very limited number of wells. Due to the influence of groundwater extraction, it was not possible to isolate NA effects from groundwater extraction influence. However, the presence of TCE degradation daughter products were identified in a large number of wells even those wells influenced by extraction.

ISM study was deployed in MW2 and 120 for 84 days using Bio-Traps obtained from Microbial Insights. The study included monitoring for natural attenuation of MC using a control unit. ^{13}C labeled MC was embedded in the Bio-traps. The results indicted no evidence of natural attenuation is taking place in MW2 for MC but some evidence of NA occurred in 120. These results indicate that high concentration areas are not amenable to natural biodegradation while natural biodegradation was observed in low concentration areas.

For this alternative, it is assumed that a monitoring program would be designed and implemented in accordance with USEPA guidance (USEPA, 1998; USEPA, 2004) to evaluate the effectiveness of NA at the site. A total of 92 monitoring wells are currently available to provide groundwater data (32 Wilcox Formation wells and 60 shallow zone wells). For MNA, monitoring wells in the Shallow Zone and Wilcox Formation would be selected for sampling.

MNA sampling would be performed as part of groundwater monitoring plans. MNA sampling would be performed quarterly for the first two years, semiannually for the next three years, then annually until the next Five-Year Review. After that, the sampling frequency may be changed to once every five years if the data suggest less frequent sampling is appropriate. For costing purposes, a 30-year monitoring program is assumed. The analytical program would consist of VOCs, metals, perchlorate, and 1,4-dioxane. The following parameters would also be included in the initial analytical program: sulfate, nitrate, nitrites, alkalinity, total organic carbon, and field tests for dissolved oxygen, redox potential, and ferrous iron. These parameters would be dropped when NA is well documented. Additional parameters that will be conducted for two events only in select Wilcox Formation wells (e.g., 18CPTMW01SW and 18CPTMW06SW for TCE and MC wells) to establish biodegradation potential include: reductive TCE and VC gene expression, dehalococcoides and dehalobacter concentration, and compound specific isotope analysis for TCE. Subsequent LTM would be limited to VOCs, metals, and perchlorate. For cost estimating purposes, 45 monitoring wells were assumed for sampling (50 samples with QC). MNA parameters for this alternative will be captured for Wilcox Formation wells. For cost estimating purposes, 5 monitoring wells were assumed for MNA sampling (8 samples with QC) for two years.

Annual reports would be prepared to document the program. The second year annual report would include a review of the first eight rounds of sampling and provide the rationale for MNA as an effective part of the remedial alternative. Sampling frequency, reporting frequency, or analytical suite may be modified based on the results of the sampling program.

5.2.2.7 Alternative 2 Duration

This alternative's lifecycle will range between 300 and 500 years. The rate limiting factors would be the desorption rate of VOCs from the low K zones and dissolution of DNAPL into the extracted groundwater. The estimated duration is expected to exceed 30 years controlled by desorption of VOCs from the soil and residual DNAPL. For cost estimation, a duration of 30 years is used.

5.2.3 Alternative 3 – Groundwater Extraction and Treatment, MNA Outside the Containment and in Wilcox Formation, LUC, and Containment

The goals of this alternative are to prevent exposure of the hypothetical future maintenance worker to contaminated groundwater at LHAAP-18/24 and to prevent migration of contaminated groundwater to Harrison Bayou. Under this alternative, further migration of source material will not be prevented or minimized (i.e., migration of contaminants from the unsaturated soil to groundwater or from DNAPL zones to groundwater), this alternative remains protective of human health and will prevent further migration of the contaminant plume in groundwater and protect surface water. To achieve these goals, this alternative uses a slurry wall to contain contaminated groundwater within the existing plume extent. Protective LUCs would be

developed and maintained to prevent use of groundwater for human ingestion until the cleanup levels are met. As a containment alternative, it is not a long-term goal within this alternative to return the groundwater to beneficial use within the bounds of the containment itself. Hence, this alternative does not satisfy one of the RAOs defined in **Section 3.0**.

Under this scenario, a slurry wall would be installed to isolate the groundwater and source areas with high perchlorate and VOC concentrations. Groundwater extraction without enhancement would be intended for gradient control rather than contaminant mass removal, so operations at the GWTP could be reduced over time. The closure cap over the UEP will be maintained in good condition, preventing erosion and maintaining vegetative cover to reduce infiltration in this area. Groundwater monitoring would be conducted to confirm that the slurry wall is functioning properly, and that contaminant concentrations are staying at or below acceptable levels outside the slurry wall. Long-term groundwater LUCs would be required for LHAAP-18/24 until cleanup levels are met for the groundwater CoCs.

For Alternative 3, the slurry wall will contain the source material, but not destroy it. The groundwater extraction will remove a small amount of source material over time. The groundwater extraction and treatment will apply to the shallow groundwater within the containment area. MNA will be applicable to the Wilcox Formation groundwater and shallow groundwater outside the slurry wall not influenced by groundwater extraction. For Alternative 3, the groundwater extraction system will not be enhanced like for the other alternatives. It is expected that the extraction and treatment system will continue to operate for 2 years at existing extraction rates, then be set at reduced operation of approximately 50 to 65% to maintain an inward and upward gradient inside the slurry wall. The groundwater extraction and treatment system would never be completely shut down. MNA outside the slurry wall would continue until TCE and perchlorate concentrations reach the cleanup level. No definite duration can be calculated for attaining the cleanup level inside the slurry wall (e.g., the time frame will exceed 200 years based on **Table 2-14** projections) and an ARAR waiver would be required for the area contained within the slurry wall.

5.2.3.1 Groundwater Containment

A slurry wall would be installed to isolate groundwater with perchlorate, VOC, and other contaminant concentrations. The surface of LHAAP-18/24 would be improved by adding additional soil in some areas and improving drainage ditches to minimize storm water run-on and infiltration. The groundwater extraction and treatment system would be kept operating, but the extraction volume (and the associated treatment volume) would be reduced over time as monitoring demonstrates that the groundwater within the slurry wall is properly contained and an inward and upward hydraulic gradient is imposed.

5.2.3.1.1 Lateral Containment

The slurry wall would surround the area with the highest concentrations (e.g., > 100 µg/L for perchlorate and > 10 µg/L for TCE) including specifically the high perchlorate concentrations at ICT-11, 18CPTMW22 (plugged in September 2014), ICT-12E, MW-8, MW-5, and 18WW17; the high MC concentrations at MW-2, ICT-8 and ICT-12E; and the high TCE concentrations at EW-1, MW-2, MW-8, and ICT-12E. To encompass these locations, the slurry wall will have to surround the containment area and extend out to the northeast to encircle 18WW17, out to the

southwest to encircle MW-8, and to the south to encompass former well 18CPTMW22. **Figure 5-3** shows the projected outline of the area to be encircled by the slurry wall. As shown, the slurry wall is approximately 6,500 ft in length. The depth of the slurry wall will vary in accordance with the depth to the clay confining layer to key into. The approximate depth to the clay layer is depicted on **Figure 5-3** along the path of the slurry wall.

Near ICT-12E, which extends to approximately 31 ft bgs, and nearby wells, there is an absence of the clay layer near that depth. This alternative assumes the slurry wall will extend beyond 30 ft because there is no evidence of presence of a confining layer to improve vertical containment in that area. There is no contamination in the Wilcox wells in the northwest area of the site outside the containment (e.g., in monitoring wells 18WW02 and 18WW06). Therefore, although a clay layer is absent in this area of the site, the potential for vertical migration then lateral migration is not likely, particularly with continued groundwater extraction.

5.2.3.1.2 Surface Improvements

To reduce infiltration, the drainage ditches at the site would be re-graded and lined, and additional soil would be added in flat areas. The existing topography promotes rapid run off from the UEP and the western corner. In contrast, the southeastern portion of the site is relatively flat and drains poorly. Therefore, this alternative includes placement and grading of borrow soil to improve the slope on the southeastern portion of the site, and upgrading approximately 5,800 linear ft of ditches at the site. The latter includes new ditches around the UEP to rapidly convey runoff away from the remainder of the site. The estimated aerial extent of the area included in this work is 720 ft by 360 ft. It is estimated that on average 2.5 ft of soil will be used to grade the area. The total volume is estimated at 24,000 yd^3.

5.2.3.2 Reduced Groundwater Extraction

Reducing the existing volume of groundwater extraction would depend on shutting off extraction points as the inward and upward gradient is established. A study of rainfall amounts versus shallow groundwater elevation will be conducted to understand and determine how much groundwater extraction would be sufficient to maintain an inward and upward gradient. This study will entail use of data loggers in 20 wells within the slurry wall area for a period of two years (to understand seasonal variability) during which shutting off of extraction points will be tested to allow system optimization. Based on this analysis, a determination of the amount of reduction of extraction rate would be completed and implemented. It will be assumed that a reduction to 65% of the initial extraction rate (i.e., 65% of 20 gpm or 13 gpm) will be plausible as a result of surface improvements conducted at the site to improve drainage and reduce infiltration rate. Further reduction to 50% of extraction rate will be assumed at year 10 onward (i.e., eight (8) years after the two (2) year study is completed).

Extraction is expected to continue indefinitely at a reduced rate. Implementation of this alternative requires that no release of treated groundwater to the Burning Ground No. 3 occurs. Management of treated groundwater by discharging to Harrison Bayou and to the INF Pond will be conducted.

Ongoing monthly measurement of groundwater levels in the shallow zone will allow evaluation of groundwater capture zone and stability (i.e., after completion of the two year study).

Measurements of groundwater elevation in the Wilcox Formation will allow continued assessment of vertical gradients.

Based on these estimates, it is expected that the GWTP will be operated for a minimum of 30 years. The current GWTP is nearly 17 years old and is aging requiring frequent maintenance with anticipated more maintenance requirements with recapitalization for major item replacement in the near future. Additionally, the existing GWTP is oversized with a design capacity of up to 300 gpm while current operations recover an average flow of 20 gpm. The plant is currently operated one day per week and idling the remainder of the week with the exception of the FBR which operates continuously. Idling of the plant results in stagnant conditions creating additional maintenance problems associated with corrosion of equipment, deposition of precipitates in tanks, piping, pumps, valves, etc., and freeze stresses in the winter that could be avoided if operations were continuous. Due to the age of the plant, frequent maintenance requirements, and idling conditions, capitalization of a smaller foot print GWTP to replace the existing plan is recommended.

The new GWTP will be designed for a 50 gpm flow rate, which should accommodate the existing and anticipated decrease in groundwater extraction rates (deactivation of ICTs). The system will consist of the same processes of metals precipitation, VOC stripping, and a FBR for removal of perchlorate. Without replacement of TK-140 (equalization tank) and TK-630 (effluent storage tank), and without a new belt press, the cost to recapitalize the GWTP is estimated at $2.2 million with an annual operational and maintenance cost of $513,000. No major replacement is anticipated for the first 10 years with 10% of the capital cost spent once every five years thereafter for major equipment replacement.

5.2.3.3 UEP Cap Maintenance

The former UEP was closed under RCRA in 1986 and capped by 1987. The UEP cap design consisted of removing the sludge, filling the UEP with common fill, covering the common fill with 4 ft of compacted clay, then applying 1 foot of sand, covered by 1 foot of topsoil. The surface of the cap has an average slope of three percent on top while the sides have a vertical to horizontal ratio of 1:4. It is graded and equipped with a sand drainage layer to promote sheet flow runoff to minimize erosion.

This cap would continue to be monitored, maintained, and repaired, as necessary, to ensure long-term effectiveness. This includes inspections of the cap to check for erosion, settlement, and deep-rooted vegetation, and implementation of necessary repairs. Routine maintenance and repair of the cap would include actions needed to ensure that the integrity of the cap is maintained (e.g., mowing, seeding, and settlement/erosion repair).

The importance of maintaining the cap is to prevent contaminants present in the unsaturated soil from leaching to groundwater. Three locations within the UEP identified the presence of contaminants within the unsaturated zone above the water table (18CPT21, 18CPT25, and 18CPTUEP05). The highest contamination was reported in 18CPT21. The presence of the cap provides a significant protection of this soil as long as cap maintenance continues to minimize infiltration of rain water. The runoff water from the UEP cap will be drained to off-site locations to avoid infiltration of rain water inside the containment.

5.2.3.4 Land Use Control

The LUCs would be implemented to prevent any use of groundwater (other than monitoring) in both the shallow and Wilcox groundwater zones. This restriction would need to remain in place until CoC concentrations in soil and groundwater allow for unrestricted use and limited exposure.

5.2.3.5 Groundwater Monitoring and MNA

For this alternative, MNA is applicable to the contaminants left outside the slurry wall and the Wilcox Formation groundwater. The slurry wall will encompass the majority of contaminant concentrations above the cleanup levels. Wells that may contain CoCs above the cleanup level that fall outside the slurry wall (e.g., 18WW08 for perchlorate) will be monitored to ascertain that concentrations in those locations will decrease over time under NA. Similarly, concentrations in the Wilcox Formation will be monitored for CoC concentration changes over time. No NA information is available for Wilcox Formation wells at this time because the majority of Wilcox Formation wells that are impacted were installed since May 2013 and only two to three data points are available for these wells. New data will need to be evaluated for NA in the Wilcox Formation.

For this alternative, it is assumed that a monitoring program would be designed and implemented in accordance with USEPA guidance (USEPA, 1998; USEPA, 2004) to evaluate the effectiveness of NA at the site. A total of 92 monitoring wells are currently available to provide groundwater data (32 Wilcox Formation wells and 60 shallow zone wells). For MNA, monitoring wells in the Wilcox Formation and select wells outside the slurry wall in the shallow zone would be selected for NA sampling. Wells inside the slurry wall will not be included in the NA sampling program.

MNA sampling would be as part of groundwater monitoring plans. MNA sampling would be performed semi-annually for the first two years, annually for the next three years, then every two years for the next four years. After that, the sampling frequency may be changed to once every five years if the data suggest less frequent sampling is appropriate. For costing purposes, a 30-year monitoring program is assumed. The analytical program would consist of VOCs, metals, perchlorate, and 1,4-dioxane. The following parameters would also be included in the initial analytical program: sulfate, nitrate, nitrites, alkalinity, total organic carbon, and field tests for dissolved oxygen, redox potential, and ferrous iron. These parameters would be dropped when NA is well documented. Additional parameters that will be conducted for two events only in select Wilcox Formation wells (e.g., 18CPTMW01SW and 18CPTMW06SW for TCE and MC) to establish biodegradation potential include: reductive TCE and VC gene expression, dehalococcoides and dehalobacter concentration, and compound specific isotope analysis for TCE. Subsequent LTM would be limited to VOCs, metals, and perchlorate. For cost estimating purposes, 4 Wilcox monitoring wells and 12 shallow monitoring wells were assumed for sampling (20 samples with QC).

Annual reports would be prepared to document the program. The second year annual report would include a review of the first eight rounds of sampling and provide the rationale for MNA as an effective part of the remedial alternative. Sampling frequency, reporting frequency, or analytical suite may be modified based on the results of the sampling program.

5.2.3.6 Alternative 3 Duration

This alternative's lifecycle is controlled by the desorption rate of VOCs from the soil and dissolution of DNAPL with an estimated duration exceeding several hundred years. For cost estimation, a duration of 30 years is used.

5.2.4 Alternative 4 –Enhanced Groundwater Extraction Inside Containment and Ex Situ Treatment, LUC, Enhanced ISB Inside & Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, and Surfactant Enhanced DNAPL Removal

This alternative is similar to Alternative 2 (i.e., ISB, unsaturated soil excavation, LUCs implementation, enhanced groundwater extraction, and capitalization of a new GWTP) with the addition of means to enhance removal of DNAPL from the shallow zone groundwater in the two DNAPL areas of the site. The application of surfactant flushing will accelerate removal of residual DNAPL, reduce remaining CoC mass, and reduce the lifecycle of the project. **Figure 5-4** depicts this alternative. The discussion below focuses only on DNAPL removal technology as the remainder of the technologies has been described in detail in Alternative 2.

The goal for this alternative is similar to Alternative 2 but the approach presents a higher level of contaminant removal from the DNAPL areas at a more rapid rate. This alternative achieves protection to human health and the environment. Acceleration for achieving RAOs occurs because this alternative attempts to remove the major source of VOCs believed to be present in residual DNAPL form as determined by the presence of very high concentrations in groundwater and soil (discrete soil data developed in the Updated PSI Report (AECOM, 2016a)).

CoCs inside the containment area within the shallow groundwater zone would be destroyed in the target areas by enhanced in situ biotreatment. These are the areas outside the DNAPL removal areas and are selected in areas with highest groundwater CoC concentrations. Outside the containment enhanced ISB will be implemented to accelerate dissolved plume attenuation and prevent further migration of contaminants to clean groundwater and/or surface water. Similarly, enhanced ISB will be implemented at three locations in the Wilcox aquifer as described for Alternative 2.

A monitoring program would be designed and implemented to evaluate enhanced NA of VOCs and perchlorate in the shallow zone inside and outside the containment area after completion of active remediation as may be necessary. The monitoring program would also monitor for CoCs in the upper Wilcox Formation. LTM would be conducted to confirm that contaminant concentrations are being reduced to acceptable levels over time. Implementation of LUCs will be required and maintenance of the UEP cap will be conducted.

The sections below discuss surfactant flushing technology.

5.2.4.1 Surfactant Flushing Approach

A surfactant flushing treatability study geared toward DNAPLs to identify and optimize the concentrations of the most compatible surfactant(s)/electrolyte(s) mixture, and application volume to the site groundwater and soil will be required. The study will also quantify the maximum groundwater remediation removal of the contaminants while also anticipating adverse incompatibilities that may occur during field implementation. Surfactant phase behavior,

geochemical compatibility, and one-dimensional column studies are recommended for the treatability study. Each treatability test requires sediment, free product, and groundwater collected from the specific site for groundwater remediation. The tests will also determine if adverse chemicals are generated from mixing surfactants with CoCs.

Once treatability testing is completed, pilot-scale testing is recommended to better understand how well surfactant addition would be distributed in the subsurface and result in solubilization of DNAPL from both coarse and fine-grained soils (i.e., to understand limitations of distributing surfactant due to soil heterogeneity). This is an important step because the majority of the residual DNAPL was identified to occur in fine-grained soils (low K zones). Pilot-scale testing will also be used to determine whether DNAPL migration to unintended areas would occur and to determine means to prevent this potential loss of process control. If pilot-scale testing proved successful, remediation will be designed and conducted. The process entails surfactant injection in injection points installed for this process. A few days after injection of the surfactant and solubilization of residual DNAPL, extraction of groundwater under vacuum applied at extraction points (i.e., dual phase extraction) specifically installed for this process will be conducted. Surfactants facilitate contaminant removal by two primary mechanisms: first, through enhancing the mobility of the contaminant by reducing interfacial tension; and secondly by increasing contaminant solubility. Contaminant mobility, increased by interfacial tension reduction, allows the DNAPL to flow more readily through the subsurface. Contaminant solubility will also increase by the formation of micro-emulsions. Following surfactant injection--generally within 16 to 48 hours- dual phase extraction is utilized to capture the mobilized contaminant, surfactant, and the micro-emulsions formed during this process. Extracting total fluids from the formation a very short period after injection of surfactant should minimize the risk of mobilizing DNAPL or movement of DNAPL downward to the Wilcox clay. Additionally, the surfactant itself solubilizes DNAPL such that DNAPL in its original form no longer exists.

In the final phase of the process, episodic dual phase extraction is implemented to allow for “vertical” flushing of the impacted soil column. The extraction pattern varies to assure the most efficient sweep of the contaminant zone.

The extracted fluid will be very concentrated and will be disposed off site as the on-site GWTP is not designed to handle very high loads expected to be removed from the DNAPL surfactant flushing process. The volume of groundwater removed is estimated at 1 million gallons. The estimated volume will be determined after the treatability study/process design is completed. The number of injection and extraction points will be a function of the aerial extent of DNAPL area, vertical distribution of DNAPL, and site-specific limitations. For costing purposes, it is assumed that 40 injection points and 52 extraction wells will be installed for the two DNAPL areas for the surfactant flushing.

Removal of residual DNAPL via surfactant flushing and extraction is not expected to be complete, particularly due to the difficulty in surfactant distribution within the low K zones. Removal of up to 90% is plausible based on vendor information, although this has to be confirmed by pilot-scale testing.

The presence of DNAPL in the ACD area may extend farther to the north toward ICT-12E and monitoring well 120, increasing the area to be treated for DNAPL. Therefore, the cost estimate

for the DNAPL area in the vicinity of the ACD may become larger and will be considered during the remedial design phase.

5.2.4.2 Enhanced ISB Polishing

Depending on the cleanup level achieved with surfactant flushing, it is anticipated that enhanced ISB in the treated DNAPL areas be implemented in a grid fashion with 25 by 25 ft spacing. Two events as described for other enhanced ISB will be implemented. Additionally, enhanced ISB would be required in the treated DNAPL areas due to the presence of perchlorate which is not readily removed by surfactant flushing. It is anticipated that residual surfactants will be required to also enhance ISB.

5.2.4.3 Alternative 4 Duration

Because of the presence of residual DNAPL, the duration of this alternative will remain long at approximately 30 years. For cost estimation, a duration of 30 years is used.

5.2.5 Alternative 5 –Enhanced Groundwater Extraction Inside Containment and Ex Situ Treatment, LUC, Enhanced ISB Inside and Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, Thermal DNAPL Removal

This alternative is similar to Alternative 4 (i.e., ISB, unsaturated soil excavation, LUCs implementation, enhanced groundwater extraction, and capitalization of a new GWTP) with the use of ERH to address DNAPL areas instead of surfactant flushing. Note that while the focus of this discussion is on ERH, other thermal treatment technologies such as thermal conduction heating could be equally applicable. Typically, the selection as to which technology to implement is proposed by the technology vendor; particularly, when a performance-based approach is used. In this alternative, ERH was used to cost the technology. **Figure 5-5** depicts this alternative. This alternative is expected to achieve site RAOs in the shortest period of time compared to the other alternatives.

CoCs inside the containment area within the shallow groundwater zone would be reduced in the target areas by enhanced in situ biotreatment. These are the areas outside the DNAPL removal areas and are selected in areas with highest groundwater CoC concentrations. Outside the containment enhanced ISB will be implemented to accelerate dissolved plume attenuation and prevent further migration of contaminants to clean groundwater and/or surface water. Similarly, enhanced ISB will be implemented at three locations in the Wilcox aquifer as described for Alternative 2.

Removal of targeted soil will be conducted as discussed for Alternative 2. UEP cap maintenance will be implemented including LUCs to prevent use of groundwater. MNA for areas outside the influence of the treatment areas will be evaluated and implemented as discussed for Alternative 2.

A monitoring program would be designed and implemented to evaluate enhanced NA of VOCs and perchlorate in the shallow zone inside and outside the containment area after completion of active remediation as may be necessary. The monitoring program would also monitor for CoCs in the upper Wilcox Formation. LTM would be conducted to confirm that contaminant

concentrations are being reduced to acceptable levels over time. Implementation of LUCs as may be required and maintenance of the UEP cap will be conducted.

The discussion below focuses only on thermal treatment.

5.2.5.1 In Situ Thermal Treatment

The key physical and chemical properties that govern the fate and transport of chlorinated solvents, including viscosity, solubility, vapor pressure, octanol-water partition coefficient, and Henry's Law constant, are temperature dependent. The chlorinated solvent properties are generally based on a "standard" temperature of 25°C. At the higher temperatures employed during *in situ* thermal treatment, these properties change, typically in a way that enhances the treatability of the chlorinated solvents. The primary thermal effects applicable to chlorinated solvents present in the free phase, sorbed phase and the dissolved phase are summarized in the table below.

Fate and Transport Property	Effect as Temperature Increases
Liquid density	Decreases moderately (less than 100 percent)
Vapor pressure	Increases significantly (10 to 20 fold)
Liquid viscosity	Decreases significantly until boiling point and drops markedly upon conversion from liquid to vapor
Vapor Viscosity	Increases slightly as vapor temperature increases
Diffusivity	Increases
Solubility	Increases as temperature increases
Henry's Constant	Increases (more likely to volatilize from water)
Partition Coefficient	Increases (less likely to partition to organic matter in soil)
Biological Degradation	Increases (may decrease at higher temperatures)
Abiotic Degradation	Increases

Source: Derived from Davis, 1997

ERH involves the application of electrical current through the subsurface, resulting in the generation of heat. ERH uses the natural electrical resistance within the subsurface where energy is dissipated through ohmic, or resistive, losses. This manner of in situ heating allows energy to be focused into a specific source zone. When the subsurface temperature is increased to the boiling point of the pore water or the saturated media in the treatment zone, steam is generated. The steam strips contaminants from the soils and enables them to be extracted from the subsurface. In addition, contaminants are directly volatilized from unsaturated soil.

ERH is particularly suited to the treatment of lower permeability strata and to DNAPLs that have become consolidated within lower K zones with higher organic content. ERH is used to treat the lower K zones, which the steam vapors cannot penetrate rapidly (Beyke 1998).

An ERH system consists of subsurface electrodes connected to direct current through the subsurface, and a vapor extraction system to capture the volatilized water and contaminants. In some cases, groundwater extraction is also used to lower the water table within the treatment zone during initial stages of treatment (prior to temperatures exceeding the boiling point of

subsurface water) or to provide hydraulic control. Electrodes can be installed using several different drilling or direct-push techniques, including angled or horizontal methods.

Typically, utility (60 Hertz) electrical power is used with power conversion equipment to regulate voltage or to convert the phase characteristics of the power. Multi-phase heating requires additional space for a transformer (typically mounted on a standard tractor trailer), which can also be designed to include voltage controls (Beyke 1998). Vapor extraction systems are typically used to remove volatilized water and contaminants from the subsurface. The vapor extraction and aboveground treatment equipment is similar to that used with steam enhanced injection (SEI). Higher temperature conditions should be considered when designing extraction and monitoring wells and associated equipment for the treatment area. Existing equipment may require modifications or replacement to accommodate these elevated temperature conditions.

For the site, ERH will be the selected thermal remediation method due its efficiency for removing DNAPL. However, further discussion with vendors will be required to finalize the selection of thermal technology. For costing purposes, it will be assumed that 25 vapor extraction points will be used to a depth of 15 ft bgs using stainless steel material. Extraction will be conducted using a liquid ring vacuum pump and a thermal oxidizer will be used to treat the vapors. Air flow capacity is estimated at 4,000 cubic ft per minute.

Removal of residual DNAPL via thermal treatment and extraction will remove at least 99.9% according to the thermal vendors even within low K zones. Thermal treatment also enhances mobilization of organic matter from the soil to groundwater, which will act to enhance biodegradation of the CoCs. Additionally, higher ambient soil temperature imposed by the thermal treatment process during startup and cool down periods will increase the biodegradation rate by a factor of 2 for every 10 degree Celsius increase in ambient soil temperature up to approximately 25 degrees Celsius above which bacterial activity would decrease. Application of thermal treatment in the southern area of the UEP will also remove CoCs in the unsaturated zone (e.g., area represented by 18CPT21) that would otherwise be subject to excavation. Therefore, the volume requiring excavation is reduced and would be estimated by approximately 6,000 yd^3.

Groundwater extraction near the thermally treated areas might have to be ceased temporarily to reduce the groundwater flux through the area, which requires additional heating capacity.

The presence of DNAPL in the ACD area may extend farther to the north toward ICT-12E and monitoring well 120, increasing the area to be treated for DNAPL. Therefore, the cost estimate for the DNAPL area in the vicinity of the ACD may become larger and will be considered during the remedial design phase.

5.2.5.2 Enhanced ISB Polishing

Depending on the cleanup level achieved with thermal treatment for VOCs, it is anticipated that enhanced ISB in the treated DNAPL areas be implemented in a grid fashion with 25 by 25 ft spacing. Two events as described for other enhanced ISB will be implemented. Additionally, enhanced ISB would be required in the treated DNAPL areas due to the presence of perchlorate which is not readily removed by thermal treatment. Enhanced ISB application will occur when the temperature of the thermally treated area cools to below 30 degree Celsius.

5.2.5.3 Alternative 5 Duration

This alternative's lifecycle will be accelerated after DNAPL removal by ISB inside the containment within the shallow groundwater zone. The rate limiting factor would be the desorption rate of VOCs from the soil; however, the estimated duration would be less than for alternative 4 and will be assumed to be 20 years, at about 4 times the duration estimated for the adsorbed phase TCE to be remediated (**Table 2-14**). However, for cost estimation, a duration of 30 years is used.

5.2.6 Alternative 6 –Enhanced Groundwater Extraction Inside Containment and Ex Situ Treatment, LUC, Enhanced ISB Inside and Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, Enhanced DNAPL Remediation using ZVI

This alternative is similar to Alternative 5 with a different method for treating DNAPL source areas inside the containment. **Figure 5-6** depicts this alternative. This alternative will achieve RAOs in a period of time comparable to Alternative 5. The discussion below focuses only on source area treatment because the remainder of the approach is similar to Alternative 5.

CoCs inside the containment area within the shallow groundwater zone would be destroyed in the target areas by enhanced in situ biotreatment. These are the areas outside the DNAPL removal areas and are selected in areas with highest groundwater CoC concentrations. Outside the containment enhanced ISB will be implemented to accelerate dissolved plume attenuation and prevent further migration of contaminants to clean groundwater and/or surface water. Similarly, enhanced ISB will be implemented at three locations in the Wilcox aquifer as described for Alternative 2.

Within the DNAPL areas remediation will be attained via application of micron-scale ZVI directly using injection wells and direct push methods across the full depth of impact within the saturated zone.

A monitoring program would be designed and implemented to evaluate enhanced NA of VOCs and perchlorate in the shallow zone inside and outside the containment area after completion of active remediation as may be necessary. The monitoring program would also monitor for CoCs in the upper Wilcox Formation. LTM would be conducted to confirm that contaminant concentrations are being reduced to acceptable levels over time. Implementation of LUCs as may be required and maintenance of the UEP cap will be conducted.

The discussion below focuses only on DNAPL Source Areas treatment using ZVI.

5.2.6.1 DNAPL Source Areas Remediation using ZVI

Micron-scale ZVI will be injected into targeted zones using direct push tools and/or injection wells. The radius of influence of the injection point should be known to determine spacing of injection locations and allow overlap of radii of influence. For cost estimation, it is assumed that one injection point is conducted for every 100 ft^2 area (radius of influence of approximately 5.5 ft). The amount of ZVI should be such that excess quantities of iron is introduced to account for the mass of chlorinated VOCs but also for 'natural demand' to ascertain that sufficient residual remains in the formation to treat chlorinated VOCs associated with diffusion from fine-grained soils that would occur over time. A quantity of 0.01 lb/lb of micron-scale ZVI to formation soil

is assumed based on treatability testing completed at SiRem laboratory for this site (**Appendix C**). **Figure 5-6** depicts locations where DNAPL remediation will be conducted. Indication of distribution of ZVI can be determined using pH, ORP, and dissolved iron concentrations. Re-application of ZVI might be required should conditions indicate absence of reducing conditions (e.g., elevation of ORP). ZVI results in creating a very reducing conditions in the subsurface (i.e., ORP < -400 mV). The creation of a very reducing condition in the subsurface creates the condition for effective natural biodegradation or enhanced ISB. It was observed in the laboratory, the generation of hydrogen resulted in fermentation of CM and even in reduction of perchlorate concentration associated with bacteria mediated reduction of perchlorate.

Injection of ZVI into DNAPL areas could have the unintended consequences of mobilizing DNAPL to unimpacted areas by virtue of creating a higher hydraulic head within the injection locations. This would be managed by minimizing the volume of fluid used to inject the ZVI, strategically placing the injection points starting at the perimeter of the area of impact and moving inward, and use of monitoring wells in the areas of injection particularly near the perimeter of the injection area to monitor CoC concentrations.

For cost estimating purposes, two applications of ZVI treatments are assumed with the second injection equal to 40% of the first injection due to mass and volume reduction associated with the first injection. After the injections, it is assumed that MNA will control any remaining dissolved CoCs in those areas. Due to the difficulty in distributing the injected ZVI in low K zones, ZVI application is assumed to remove no more than 70% to 80% of the mass of VOCs per application.

The presence of DNAPL in the ACD area may extend farther to the north toward ICT-12E and monitoring well 120, increasing the area to be treated for DNAPL. Therefore, the cost estimate for the DNAPL area in the vicinity of the ACD may become larger and will be considered during the remedial design phase.

5.2.6.2 Enhanced ISB Polishing

Depending on the cleanup level achieved with ZVI for VOCs and perchlorate, it is anticipated that enhanced ISB in the treated DNAPL areas be implemented in a grid fashion with 25 by 25 ft spacing. Two events as described for other enhanced ISB will be implemented. Additionally, enhanced ISB would be required in the treated DNAPL areas due to the presence of perchlorate which is not readily removed by ZVI treatment.

5.2.6.3 Alternative 6 Duration

This alternative's lifecycle will be accelerated after DNAPL remediation by ZVI application within the source areas and ISB inside the containment area within the shallow groundwater zone. The rate limiting factor would be the desorption rate of VOCs from the soil; however, the estimated duration is estimated at 30 years, at about 6 times the duration estimated for the adsorbed phase TCE to be remediated (**Table 2-14**). For cost estimation, a duration of 30 years is used.

6 DETAILED ANALYSIS OF ALTERNATIVES

This section presents and assesses relevant information that provides the basis for selecting an alternative. **Section 6.1** provides an overview of the evaluation criteria. The detailed analysis begins in **Section 6.2** in which each alternative is individually evaluated according to the evaluation criteria identified in the NCP (40 CFR 300.430). Following the individual analysis, the alternatives are compared in relation to the two threshold criteria and then the alternatives are assessed regarding the five balancing criteria, highlighting the key advantages, disadvantages, and trade-offs that are considered as part of the evaluation process (**Section 6.3**).

6.1 Overview of the Evaluation Criteria

CERCLA, Section 121, as amended, specifies statutory requirements for remedial actions. These requirements include protection of human health and the environment, compliance with ARARs, a preference for permanent solutions that incorporate treatment as a principal element to the maximum extent practicable, and cost-effectiveness. To assess whether alternatives meet the requirements, the USEPA has identified nine criteria in the NCP (40 CFR 300.430) that must be evaluated for each alternative considered for selection (Section 300.430[e][9][iii]). Provided here are summaries of the factors that comprise the nine criteria and an overview of the approach taken by this FS to address these criteria.

6.1.1 Criterion 1: Overall Protection of Human Health and the Environment

This evaluation criterion assesses whether the alternative achieves and maintains adequate protection of human health and the environment in accordance with the RAOs established in **Section 3.0**. Because the scope of this criterion is broad, it also reflects the discussions of the subsequent criteria, including long-term effectiveness and permanence, and short-term effectiveness. Evaluation of this criterion describes how site risks associated with each exposure pathway are eliminated, reduced, or mitigated through treatment, engineering, or LUCs. This criterion also considers whether an alternative poses an unacceptable short-term or cross-media effect.

6.1.2 Criterion 2: Compliance with ARARs

This criterion addresses compliance with promulgated federal and state environmental requirements. The detailed analysis summarizes which requirements are applicable or relevant and appropriate to an alternative and how the alternative meets these requirements. If an alternative cannot meet a requirement, a determination can be made that a waiver under CERCLA may be appropriate, and a basis for justifying the waiver is presented. ARARs consist of two sets of requirements – those that apply and those that are relevant and appropriate. In certain cases, standards may not exist that address the proposed action or the CoCs. In such cases, non-promulgated advisories, criteria, or guidance developed by the USEPA or other federal agencies or states can be TBCs. There are three types of ARARs; chemical-specific, location-specific, and action-specific. The chemical-, location- and action-specific ARARs are presented in **Section 3.2**.

6.1.3 Criterion 3: Long-Term Effectiveness and Permanence

This criterion evaluates the extent to which an alternative achieves an overall reduction in risk to human health and the environment after the RAOs are met. The criterion considers the degree to which the alternative provides sufficient long-term controls and reliability to prevent exposures that exceed protective levels for human and environmental receptors. The principal factors addressed by this criterion include magnitude of residual risk and the adequacy and reliability of controls to address such risk. This criterion also addresses the uncertainties associated with these factors.

The evaluation of adequacy and reliability of controls assesses the effectiveness of any treatment, containment, or institutional measures that are part of the alternative. Factors considered include performance characteristics, maintenance requirements, and expected durability. Information and data from past performance and similar technology applications are incorporated appropriately into the evaluation. LUCs are considered where they have the potential to improve the effectiveness of engineered measures.

6.1.4 Criterion 4: Reduction of Toxicity, Mobility, or Volume through Treatment

This criterion reflects the statutory preference that remedial alternatives contain a principal component that substantially reduces toxicity, mobility, or volume of hazardous substances through treatment. The evaluation regarding this criterion considers the extent to which alternative technologies can effectively and permanently fix, transform, immobilize, or reduce the volume of waste materials and contaminated media.

6.1.5 Criterion 5: Short-Term Effectiveness

This criterion addresses the effects of the construction and implementation phases of the alternative until the RAOs are achieved. The evaluation regarding this criterion considers the effect on human health and the environment posed by operations conducted during the remedial action phases. Both the potential effect and associated mitigative measures are examined for maintaining protectiveness for the community, remediation workers, and environmental receptors throughout the duration of activities.

Potential short-term risks to the public include inhalation of constituents that may be released during waste removal and treatment operations, and contaminant exposure and physical injury during waste transport off site. Potential short-term risks to workers include direct contact and exposure during construction, waste handling, and transportation; physical injury or death during construction and transportation activities; and nonremediation worker exposures to airborne contaminants during waste and soil removal operations. Alternative analyses also include a description of mitigating measures such as engineering and LUCs that are expected to minimize potential risks to the public and workers. This evaluation also addresses the anticipated duration of remedial activities.

6.1.6 Criterion 6: Implementability

This criterion examines the technical and administrative factors affecting implementation of an alternative and considers the availability of services and materials required during implementation. Technical factors to be assessed include the ease and reliability of construction

and operations, the prospects for implementing a future action, and the adequacy of monitoring systems to detect failures. Administrative factors include meeting the substantive requirements of permits and coordination requirements between the lead agency and regulatory agencies. Service and material considerations include TSD capacities, equipment and operator availability, and prospective technology applicability or development requirements.

The assessment of technical feasibility examines the performance history of the technologies in direct applications or considers the expected performance for similar applications. Uncertainties associated with construction, operation, and performance monitoring are also addressed.

The evaluation of administrative feasibility includes a discussion of those actions required to coordinate with regulatory agencies to establish the framework for complying with key substantive technical requirements that must be met by an alternative. Additionally, those alternatives that include off-site transportation of waste are reviewed to assess the feasibility of off-site disposal.

The availability of services and materials is addressed by analyzing the material components of the proposed technologies to determine the locations and quantities of those materials, and by reviewing process operations to identify special services, operator skills, or training required to readily implement the process.

The NCP requires that the evaluation of the relative administrative feasibility of each alternative include "…activities needed to coordinate with other offices and agencies, and the ability and time required to obtain any necessary approvals and permits from other agencies (for off-site actions). CERCLA, Section 121(e), stipulates that no deferral, state, or local permit shall be required for the portion of any removal or remedial action conducted entirely on site." An action must satisfy the substantive requirements of the permits that will otherwise be required.

6.1.7 Criterion 7: Cost

Cost estimates are included for each remedial alternative. The estimates are based on feasibility level scoping and are intended to aid in making project evaluations and comparisons among alternatives. The estimates have an expected accuracy of +50 to –30 percent for the scope of the action described in **Section 5.0** for each alternative. The estimates are divided into capital cost and O&M cost and are developed according to an assumed schedule for the various activities based on similar project experience.

Capital costs are defined as those expenditures required to initiate and install an alternative. These are short-term costs and are exclusive of costs required to maintain the action throughout the project lifetime. Capital costs consist of direct and indirect costs. Direct costs include construction costs (material, labor, and equipment to install an action), service equipment, process and new process buildings, utilities, and waste disposal costs. Indirect costs include design engineering, inspection, project integration, project administration and management, and project contingencies.

O&M costs are long-term costs associated with ongoing remediation at a site. These costs occur after construction and installation are completed. The costs include labor, materials, utilities, and services required to monitor, operate, and maintain the facilities for a period of up to 30 years.

The estimated present worth of each remedial alternative is determined on a discount rate of three (3) percent and a base O&M and monitoring period of up to 30 years, unless the alternative evaluated is expected to be complete in less than 30 years.

Appendix D presents detailed cost estimates for each remedial alternative.

6.1.8 Criterion 8: State Acceptance

State acceptance of an alternative will be evaluated in the PP issued for public comment. Therefore, this criterion is not considered in this Revised FS. However, the Texas Commission on Environmental Quality (TCEQ) as an FFA party will review and provide concurrence on this Revised FS.

6.1.9 Criterion 9: Community Acceptance

Community acceptance of each alternative will be evaluated after a PP is issued for public comment. Therefore, this criterion is not considered in this Revised FS.

6.2 Individual Analysis of Alternatives

6.2.1 Alternative 1 – No Action Alternative

Under the no action alternative, no further action would be taken at LHAAP-18/24 to control human exposure to contaminated groundwater or to monitor potential groundwater impacts to surface water. The contaminated groundwater would remain in place without the implementation of any contaminant removal, treatment, or containment. The groundwater extraction and treatment system would be shut down. The LUCs to prevent access to the sites will not be established or will be discontinued. No environmental monitoring will occur. It is assumed that the public and ecological species could access the area. This alternative provides a baseline for comparison purposes.

6.2.1.1 Overall Protection of Human Health and the Environment

The no action alternative would not achieve the RAOs for LHAAP-18/24. This alternative provides no control of exposure to the contaminated groundwater and no reduction in the risks to hypothetical human receptors for current and future land use scenarios. Risks to hypothetical groundwater receptors would exceed the USEPA-established threshold for acceptable incremental lifetime cancer risk of 1×10^{-4} for carcinogens or an HI of 1 for noncarcinogens from exposure to groundwater. The contaminants causing the greatest amount of risk are perchlorate and VOCs in the groundwater.

While there is no evidence that the high levels of contamination within LHAAP-18/24 are affecting Harrison Bayou, the no action alternative would cease the current hydraulic containment while providing no safeguards to ensure that the contaminants do not migrate to the surface water or allow further migration of groundwater contaminant plume. This alternative does not manage source materials and would not prevent migration of contaminants from unsaturated soil to groundwater or from residual DNAPL areas to groundwater. The no action alternative also provides no means of verifying that the mass of contamination within the saturated zone would ever be depleted and the groundwater returned to beneficial use.

6.2.1.2 Compliance with ARARs

CERCLA, Section 121, cleanup standards, including compliance with ARARs, apply only to actions the USEPA determines should be taken under CERCLA, Sections 104 and 106 authority. A no action decision will be made when no action is deemed necessary to reduce, control, or mitigate exposure because the site does not present a threat to human health and the environment, or because any action taken will worsen the negative effects on human health and the environment. Because no remedial activities are associated with this alternative, compliance with chemical-specific ARARs would not be met. Since no remedial activities will be conducted, action-specific and location-specific ARARs, if applicable, will not apply.

6.2.1.3 Long-Term Effectiveness and Performance

6.2.1.3.1 Magnitude of Residual Risk

The no action alternative would not provide an effective or permanent long-term solution. Soil exposure generated a carcinogenic risk of 5.0×10^{-7} and an HI of 0.038 for the hypothetical future maintenance worker. These risks and hazards from soil are acceptable. Soil in the unsaturated zone and in the saturated zone harbor additional contamination that will enter the groundwater over time, and the no action alternative would not address that source of contamination.

The residual risk and toxicity from groundwater exposure under a no action alternative would be unacceptable at LHAAP-18/24. For the hypothetical future maintenance worker, hypothetical groundwater exposure routes account for over 99 percent of the overall carcinogenic and non-carcinogenic risks, generating a carcinogenic risk of 4.4×10^{-1} and an HI of 3,200. These risks were conservatively calculated for a hypothetical future maintenance worker ingesting the groundwater. Currently, the groundwater at LHAAP-18/24 is not used for drinking water, and it is not anticipated to be used for drinking water under a national wildlife refuge future use scenario.

6.2.1.3.2 Adequacy and Reliability of Controls

The no action alternative would not establish or maintain any LUCs at LHAAP-18/24 and, therefore, will not reduce the existing site risks posed by contaminated groundwater if it were to be used at the site. However, groundwater use is hypothetical, and no actual use is envisioned based on current land use and anticipated future land use.

Based on the risk assessment (Jacobs, 2002), groundwater contamination has not resulted in unacceptable risk from surface water. However, the no action alternative would discontinue the current hydraulic containment, while providing no monitoring to check for future contaminant migration toward the surface water. The no action alternative does not provide adequate or reliable controls for exposure to contaminated media at the site or for cross-media contamination.

6.2.1.4 Reduction of Toxicity, Mobility, or Volume through Treatment

Implementation of the no action alternative will not reduce toxicity, mobility, or volume of contaminants because this alternative does not employ treatment.

6.2.1.5 Short-Term Effectiveness

Under the no action alternative, no remedial action would be taken; therefore, the short-term effectiveness criterion is not applicable to this alternative. The no action alternative would not cause any added short-term risks to remediation workers, the community or the environment.

6.2.1.6 Implementability

The no action alternative is inherently implementable from a technical perspective. However, it would involve shutting down the groundwater extraction and treatment system, which is likely to be administratively unacceptable. The system was implemented under an interim ROD executed by the U.S. Army and approved by the USEPA with concurrence from the state of Texas. While conditions have improved since the 1995 interim ROD, those conditions do not yet warrant shut down of the current groundwater extraction and treatment system.

6.2.1.7 Cost

There are no costs associated with the no action alternative, assuming that ceasing groundwater extraction and GWTP operation does not involve dismantling and decommissioning actions.

6.2.2 Alternative 2 –Enhanced Groundwater Extraction Inside Containment and Ex Situ Treatment, LUC, Enhanced ISB Inside & Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal

This alternative consists of the following major components:

- Continued use of the existing groundwater extraction system with enhancements (reactivate two existing ICTs) until CoC concentrations are low enough that MNA can address remaining contamination within and outside the containment area.
- Replacement of the existing GWTP with a new GWTP with the contingency to treat for 1,4-dioxane.
- Excavation of unsaturated soil exceeding groundwater protection-industrial MSC (GWP-Ind). The estimated cost to excavate soil beneath the UEP is included in this alternative and could be implemented in the future (e.g., depending on the results of the Five Year Review of the groundwater remedy).
- Implementation of ISB of shallow zone groundwater outside the containment area at several locations; in the Wilcox Formation at three locations, and inside the containment at five locations.
- Implementation of groundwater extraction and removal of residual DNAPL in two distinct areas inside the containment area at the site.
- Maintenance of existing cap over the former UEP.
- Long-term LUCs to restrict and monitor groundwater use at the site.

6.2.2.1 Overall Protection of Human Health and the Environment

6.2.2.1.1 Protection of Human Health

Existing soil concentrations are protective of a hypothetical future maintenance worker, but existing groundwater concentrations pose a potential risk.

This alternative would achieve the RAOs for LHAAP-18/24. Implementation of the LUCs would prevent human access and exposure to groundwater that poses an unacceptable risk to human health until the remedy achieves the RAOs. The LUCs would include land use notification at the Harrison County courthouse and periodic surveillance of LHAAP-18/24 to ensure that use restrictions are not being violated. The U.S. Army would include the notice with any transfer letter to the USFWS for the intended future use as a national wildlife refuge. If transferred out of U.S. government control, deed restrictions would be placed on the property to prohibit or restrict property uses that may result in exposure to groundwater (e.g., drinking water well installation).

With enhanced groundwater extraction inside the containment, implementation of ISB on three (3) sides outside the containment, five (5) Locations inside the containment, and in the Wilcox Formation, removal of potential unsaturated source soils, and remediation of secondary source areas in the saturated soil inside the containment area in two distinct areas (former UEP and former ACD), this alternative should accelerate the process of achieving the RAOs. No reliance on NA is proposed for this alternative. Since NA is occurring at the site, its use as part of the remedy is inevitable. NA inside the containment is a feasible option to polish the residual CoCs remaining after groundwater extraction operation ceases.

Groundwater use restrictions would remain in place until groundwater extraction and eventually NA reduces contaminant levels to allow unrestricted use and unlimited exposure.

A monitoring program that would track the continual attenuation of the groundwater CoCs and verify that contamination is not reaching Harrison Bayou will be implemented. The LTM program would provide information to support Five-Year Reviews and the termination of the remedy when cleanup levels have been met.

Because MNA is not currently a viable alternative throughout the entire containment area, the enhanced groundwater extraction and treatment system would continue to be operated to prevent migration of CoCs from the containment area and reduce the concentrations of those CoCs over time inside and outside the containment. Over the long term, extraction and treatment would eventually achieve concentrations throughout the containment area and outside the containment area that could be addressed via NA. At that point, the extraction and treatment system would be shut down.

6.2.2.1.2 Protection of the Environment

Alternative 2 would adequately protect the environment. The Installation-Wide Baseline Ecological Risk Assessment did not identify potential risk to ecological receptors at LHAAP-18/24 and the BERA Addendum completed in 2014 (AGEISS, Inc., July 8, 2014) did not change the conclusion of the 2007 BERA. Should there have been any ecological risk, it would have been expressed by this point in time.

This alternative includes removal of unsaturated soil and residual DNAPL sources, thus reducing or eliminating the threat of additional impact to groundwater. The alternative also prevents groundwater from impacting surface water, thus providing protection from exposure to the environmental receptors.

6.2.2.2 Compliance with ARARs

6.2.2.2.1 Chemical-Specific ARARs

This alternative would achieve the cleanup levels for groundwater contaminants that exceed their respective ARARs since the CoCs are being removed by the enhanced groundwater extraction and treatment system inside the containment and by enhanced ISB inside and outside the containment. Application of groundwater extraction within the residual DNAPL areas and removal of impacted unsaturated soil will also reduce or remove the CoCs towards achieving the chemical-specific ARARs. The estimated restoration time frames for this alternative are very long for groundwater and residual DNAPL but immediate for removing unsaturated soil source.

For Alternative 2, it is expected that the extraction and treatment system will continue to operate indefinitely (> 300 years inside the containment) to extract the soluble, adsorbed, and DNAPL mass from within the containment. This time frame is driven by the mass of VOCs in DNAPL areas and the limitation associated with dissolution of DNAPL and all adsorbed mass into the groundwater phase (diffusion limitation of low K zones).

The duration to achieve RAOs for groundwater outside the containment area in association with ISB will be short (3-5 years) but will be limited to the areas influenced by the ISB biobarriers. Enough substrate will be added to last for two years for each of two applications. Therefore, the coverage area would include a two year transport distance downgradient of the areas targeted for ISB. Additional injections will be performed after the first five years if the data indicate the need for additional substrate.

Since use of groundwater as a water supply is unlikely based on future land use at LHAAP-18/24, the time frame to achieve groundwater ARARs could be considered acceptable. Based on the risk assessment (Jacobs, 2002) and surface water sampling results, groundwater contamination has not led to unacceptable risk from surface water.

6.2.2.2.2 Location-Specific ARARs

No location-specific were identified for LHAAP-18/24.

6.2.2.2.3 Action-Specific ARARs

Activities that would be conducted under this alternative would comply with all action-specific ARARs. Extraction of groundwater will be treated and discharged in accordance with Section 402 of the CWA. ISB has been implemented at LHAAP previously and does not result in generating waste or air emissions. It typically is conducted using direct push tools to inject the substrate into the groundwater. The substrate and nutrients are food grade and state coordination is required. Bacterial formulations have been in use for some time and have been proven to be benign to the environment. Soil excavation could result in particulate emissions that would be controlled by wetting excavation areas and conducting air monitoring with established action levels. Stormwater best management practices would be developed and implemented. Excavated

soils and soil cuttings from well installation will be characterized before disposal, stored in appropriate containers, and characterized for disposal in a protective landfill suitable to the class of waste. The wells will be constructed in accordance to established industry standards.

6.2.2.2.4 Non-ARAR Procedural Considerations

Activities that would be conducted under this alternative are similar to current activities of groundwater extraction, treatment monitoring, and discharge and would comply with all procedural considerations described in **Table 3-3**. ISB source area remediation, and soil excavation will be implemented in areas that have already been disturbed. No activities would take place in sensitive environments such as wetlands, and no impacts to archeological resources or threatened and endangered species are anticipated. Compliance with the substantive requirements with waste generation, temporary storage, characterization, and off-site disposal are being carried out at this site and will be complied with during implementation of the remedy.

6.2.2.3 Long-Term Effectiveness and Permanence

6.2.2.3.1 Magnitude of Residual Risk

The risks from exposure to soil are already within the target risk range and below an HI of 1 for a hypothetical future maintenance worker.

The implementation of LUCs under this alternative would prevent direct contact by human receptors with the groundwater at LHAAP-18/24, thus minimizing the potential risk posed by groundwater contamination. Extraction of groundwater will result in continuous reduction in contaminant mass and mobility yielding reduction in overall risk to human health. Implementation of residual DNAPL source remediation, soil excavation, and ISB will also result in reduction in CoC mass and mobility, reducing overall risk to human health. Once the RAOs are achieved, complete reduction of risk to human health will be attained.

The occurrence of NA as determined in areas inside (e.g., presence of daughter TCE products) and outside the containment to the northwest and southwest will continue to reduce risk during and after groundwater extraction ceases. Further, groundwater is currently not used and is not anticipated to be used in the future due to 1) the low yield expected from thin discontinuous sand lenses, 2) the proposed future land use, and 3) implementation of groundwater use restrictions.

6.2.2.3.2 Adequacy and Reliability of Controls

The implementation of LUCs would protect potential human receptors from exposure to contaminated groundwater at LHAAP-18/24 and ensure that site use is consistent with the hypothetical future maintenance worker scenario. The adequacy and reliability of groundwater extraction and treatment system would depend on proper maintenance and operation. The system would be operated until such time as CoC concentrations are suitable for cessation of operation. The reliability of LUCs would depend on the long-term maintenance of the controls. Maintenance of the LUCs to restrict access to groundwater, would be required until cleanup levels are achieved. Because the future use of the site is by a federal agency as a refuge, LUCs are highly effective. Periodic maintenance and Five-Year Reviews will ensure that the restrictions are enforced and remain effective. The Five-Year Reviews might indicate the need for components of this alternative to be maintained, modified, or replaced.

DNAPL source area removal by groundwater extraction might be effective in removing additional mass of contaminants but it is not expected to achieve the RAOs. The extraction of groundwater results in mobilizing DNAPL by enhancing solubilization. Because no additional remediation is included in this remedy for the residual DNAPL source area (e.g., enhanced ISB), this alternative would not result in acceptable decrease in residual risk and will rely on LUCs implementation to manage risk of exposure at the site.

ISB for reduction of perchlorate and VOCs in shallow groundwater inside and outside the containment provides a permanent remedy by complete destruction of the CoCs. ISB will be implemented two times to ensure that any rebound that may occur or areas that are not treated receive additional treatment. Because the major source of CoCs located outside the containment is sourced from groundwater migration, ISB will be effective in reducing the contaminants and little to no rebound is expected. No maintenance is required between ISB applications.

Soil excavation and disposal is a very well established process and should completely remove residual CoCs in the unsaturated soil.

6.2.2.4 Reduction of Toxicity, Mobility, or Volume through Treatment

This alternative has five elements that will reduce the toxicity, mobility, and volume of the contaminants in the LHAAP-18/24 groundwater:

- Operation of an enhanced groundwater extraction and treatment system to extract groundwater from within the containment area
- Extraction of residual DNAPL in the saturated soil to mobilize and extract DNAPL
- Implementation of ISB in shallow zone groundwater inside and outside the containment and in the Wilcox aquifer
- Excavation of unsaturated source soil
- NA mechanisms including biodegradation (while this is not relied on as a main remedial action, its natural occurrence and benefits are inevitable)

These components satisfy the CERCLA statutory preference for remedial actions that permanently reduce contaminant toxicity, mobility, or volume through treatment. The reductions would be verified through monitoring.

6.2.2.5 Short-Term Effectiveness

6.2.2.5.1 Protection of the Community during Remedial Action

This alternative is protective of the surrounding community during remedy implementation primarily because all activities would occur on site with very little disturbance of contaminated material. ISB has been implemented at LHAAP previously and implementation at LHAAP-18/24 creates little disturbance as the majority of the process is conducted below ground. Vehicular traffic for equipment and materials delivery for in situ treatment would occur. If a spill occurs, which contains food grade substrate, which is harmless to the community, it could be contained and should not impact the surrounding communities. Vehicular traffic associated

with soil excavation and disposal would also be of concern and plans to minimize impacts will be taken.

Well installation activities have been implemented previously at the site without creation of hazards to the community. Groundwater extraction and treatment is also an on-going operation and does not pose hazards to the community as determined via monitoring air and water.

6.2.2.5.2 Protection of the Workers during Remedial Action

Short-term risks to human health or the environment would exist during implementation of this alternative. ISB implementation using a direct push tool, soil excavation, the operation of the GWTP, and groundwater sampling activities might expose workers to contaminants in soil and groundwater. Exposure to heavy equipment is also possible. Well installation and trenching activities for pipelines and the operation of the GWTP might expose workers to contaminants in soil and groundwater. Proper implementation of a comprehensive health and safety program would minimize risks to workers associated with this alternative. These activities have been implemented and some continue to be implemented without adverse effects on site workers.

6.2.2.5.3 Short-Term Environmental Effects

Minor clearing and grubbing at LHAAP-18/24 would be required to maintain access to monitoring wells or for access of DPT equipment for ISB implementation; since the majority of these areas have been cleared in the past, it is unlikely that there are any sensitive species that would be impacted. If any sensitive areas were found, the appropriate regulation would be followed. The implementation of proper engineering controls would minimize the risk of environmental impacts.

6.2.2.5.4 Duration of Remedial Activities

The anticipated duration of this remedial alternative depends on the groundwater extraction and treatment system achieving reductions of CoCs concentrations in groundwater to below the cleanup levels. These levels of CoCs in the shallow groundwater are not expected to be achieved within the 30-year time frame established for analyzing the alternatives.

Perchlorate, metals and VOCs detected in the groundwater are expected to continue to attenuate by operation of the enhanced groundwater extraction and treatment system and by NA. Influent and effluent concentrations as well as selected monitoring wells would continue to be monitored as part of the operation of the groundwater extraction and treatment system. These monitored concentrations will demonstrate that the remedy is operating properly and successfully (OPS).

LTM would be implemented quarterly for the first two years, semiannually for the next three years, then annually for the next five years, and once every two years thereafter. For costing purposes, a 30-year monitoring program is assumed. Until cleanup levels are met, monitoring would be needed to determine trends in groundwater contamination levels and effectiveness of the remedial action.

It is expected that the extraction and treatment system will continue to operate indefinitely (> 500 years inside the containment) to extract the soluble, adsorbed, and DNAPL mass from within the containment. This time frame is driven by the mass of VOCs in DNAPL areas and the

limitation associated with dissolution of DNAPL into the groundwater phase even under induced advective flow through the DNAPL zone.

Outside the containment area, the time frame to achieve RAOs will be shorter (5 to 10 years) because less mass is present in that area and the majority of the mass is associated with groundwater migration (i.e., present originally in the dissolved phase and easier to extract). Evaluation of performance of ISB outside the containment will be determined when data are collected.

The length of time to reach cleanup levels is probably longer for this alternative than for the other active alternatives, and there is uncertainty inherent in implementing any remedy over such a long timeframe.

The duration of implementation of soil removal is less than one month. The duration to install extraction wells within the residual DNAPL areas and extraction systems would take several months. Each ISB event is conducted over several weeks and collectively ISB will take several months to implement. Reactivation of ICT 6 and ICT 9 will take a few weeks to implement.

6.2.2.6 Implementability

6.2.2.6.1 Technical Feasibility

All components of this alternative are readily implementable. ISB and associated equipment and reactivation of ICTs have been previously implemented at this site or other sites at LHAAP. ISB treatment has been used at sites throughout the U.S. for a number of years. Injection techniques and equipment are well developed. Installation of new extraction wells and associated equipment and reactivation of ICTs have been previously implemented. The ongoing operation of the existing groundwater extraction and treatment system demonstrates this capability. All equipment, services and materials are readily available to conduct the activities for this alternative.

6.2.2.6.2 Administrative Feasibility

All actions under this alternative would be implemented on the site and thus do not require permits, though substantive provisions of permits that would otherwise be required are considered to be ARARs such as discharge of treated water to surface water meeting the established discharge limits and ISB and surfactant introduction meeting underground injection control requirements. By legal agreement (i.e., the FFA), the U.S. Army shall submit to the USEPA and TCEQ a Responsiveness Summary and ROD. Following consideration of any comments by TCEQ, the ROD will be finalized jointly by the U.S. Army and USEPA. By addressing the identified ARARs in the ROD and subsequent documents, it is anticipated that the alternative would adequately address all administrative barriers.

LUCs, although administratively implementable, would require the development of an implementation plan as part of the remedial design, and internal notices to relevant regulatory offices of the existence of the LUCs. Approval by the USEPA and the State of Texas is required prior to the significant modification or termination of a LUC, implementation actions, or modification of land-use by the U.S. Army. The U.S. Army must also seek concurrence from the

USEPA and the State of Texas prior to any action that may disrupt the effectiveness of the LUCs or any action that may alter or negate the need for LUCs.

Technology and skilled labor and equipment are available to implement this remedy including equipment and material for ISB, to install extraction wells, complete all electrical, control, and water hookups, and to excavate, contain, transport, and dispose of excavated soil. Technology, skilled labor, equipment, and material are available to operate and maintain the GWTP or to design, construct, and operate a new GWTP. Labor, tools, and methods are established for monitoring groundwater and air.

6.2.2.7 Cost

The total net present value cost of Alternative 2 is approximately $34.16 million. The details of the cost estimates for all of the alternatives are presented in **Appendix D**. This represents the 30-year cost.

6.2.2.7.1 Direct Capital Cost

The net present value capital cost is estimated at $14.56 million. Capital costs include recapitalization of a new GWTP including contingency use of advance oxidation technology for treating 1,4-dioxane, major replacement every five years beginning on year 10 for the lifecycle of the GWTP, excavation and disposal of unsaturated soils including the area under the UEP (assumed in year 6 for cost estimating purposes), implementation of additional extraction in the residual DNAPL areas, implementation of EISB, and reactivation of two ICTs. The capital cost also includes activities associated with LUCs and the work plan, regulatory documents, and a closure report.

6.2.2.7.2 O&M Cost

The net present value O&M cost is estimated at approximately $19.6 million. The O&M cost includes operation of the enhanced groundwater extraction and treatment system, monitoring for performance and MNA parameters in groundwater, and LUCs surveillance to verify continued industrial use. The LTM would support the required CERCLA Five-Year Reviews.

6.2.3 Alternative 3 – Groundwater Extraction and Treatment, MNA Outside the Containment and in Wilcox Formation, LUC, and Containment

This alternative consists of the following major components:

- Continued use of a reduced groundwater extraction system for hydraulic control.
- Replacement of the existing GWTP with a new GWTP with the contingency to treat for 1,4-dioxane.
- Installation of a slurry wall for containment of groundwater.
- Improvements to the soil cover to promote drainage and reduce infiltration.
- Maintenance of existing cap over the former UEP.
- MNA for groundwater contamination within the Wilcox Formation and outside the slurry wall.

- Long-term LUCs to restrict and monitor groundwater use at the site.

6.2.3.1 Overall Protection of Human Health and the Environment

6.2.3.1.1 Protection of Human Health

Existing soil concentrations are protective of a hypothetical future maintenance worker, but existing groundwater concentrations pose a potential risk.

This alternative would achieve the primary RAO for LHAAP-18/24 by preventing exposure to contaminated groundwater. Construction of the slurry wall, and properly keying it into the confining layer (majority of slurry wall path), would ensure that the contamination is contained. Improvement of the current soil cover and drainage features would minimize infiltration into the soil while continued operation of the groundwater extraction system would create an inward hydraulic gradient. These features would further reduce opportunity for contaminant migration and prevent the contaminants located within the slurry wall from migrating to surface water. While the slurry wall would not prevent or minimize migration of contaminants from source materials in the saturated and unsaturated zones to groundwater, the slurry wall will contain additional contaminants migrating to shallow groundwater inside the containment area.

Implementation of the LUCs would provide the following:

- Prevent human access and exposure to groundwater that poses an unacceptable risk to human health
- Prohibit activities at the site that would adversely impact soil cover at the site and associated drainage features
- Require monitoring and proper maintenance of the soil cover and slurry wall

The LUCs would include land use notification at the Harrison County courthouse and periodic surveillance of LHAAP-18/24 to ensure that use restrictions are not being violated. The U.S. Army would include the notice with any transfer letter to the USFWS for the intended future use as a national wildlife refuge. If transferred out of U.S. government control, deed restrictions would be placed on the property to prohibit or restrict property uses that may result in exposure to groundwater (e.g., drinking water well installation).

The LUCs for the area bounded by the slurry wall would remain in place indefinitely. Groundwater use restrictions outside the slurry wall would remain in place until NA reduces contaminant concentrations to allow unrestricted use and unlimited exposure. As noted in the preliminary evaluation in **Appendix A**, NA is a viable remedial measure at LHAAP-18/24 in shallow groundwater outside the containment area but has to be established for the Wilcox Formation. The MNA program would monitor the groundwater plume and ensure that the CoCs in groundwater in areas outside the slurry wall continue to degrade or remain stable. After MNA is confirmed, the MNA program would evolve into a LTM program that would track the continual degradation of the groundwater CoCs. The LTM program would provide information to support Five-Year Reviews.

Reliance on NA is also proposed for the Wilcox Formation under this alternative. Groundwater use restrictions would remain in place until NA reduces contaminant levels outside the containment and in the Wilcox Formation to allow unrestricted use and unlimited exposure.

6.2.3.1.2 Protection of the Environment

Alternative 3 would adequately protect the environment. The Installation-Wide Baseline Ecological Risk Assessment did not identify potential risk to ecological receptors at LHAAP-18/24 and the BERA Addendum completed in 2014 (AGEISS, Inc., July 8, 2014) did not change the conclusion of the 2007 BERA. Should there have been any ecological risk, it would have been expressed by this point in time.

This alternative does not remove unsaturated soil and residual DNAPL sources, thus it does not result in reducing or eliminating the threat of additional impact to groundwater. The alternative does prevent groundwater located within the slurry wall from impacting surface water, thus providing protection from exposure to the environmental receptors but it does not prevent groundwater outside the slurry wall from migrating to surface water.

While the exposure RAO would be satisfied by this alternative, the RAO for groundwater restoration would not be met within the slurry wall itself. The slurry wall would serve to cut off contaminant migration, but there would be a reservoir of contamination within the wall that would not be depleted. The groundwater restoration RAO would need to be waived for this area.

6.2.3.2 Compliance with ARARs

6.2.3.2.1 Chemical-Specific ARARs

Within the slurry wall, this alternative would not achieve cleanup levels. However, it would ensure that humans are not exposed to concentrations that exceed the cleanup levels. Outside the slurry wall, this alternative will achieve the cleanup levels for groundwater contaminants that exceed their respective ARARs by NA. The slurry wall would be designed to encompass the majority of impacted shallow groundwater zones inside and outside the containment area. Therefore, only low concentrations of CoCs would be left outside the slurry wall containment. Assuming 1,000 µg/L perchlorate concentration remained outside the slurry wall (conservative estimate as the slurry wall would encompass the majority of the perchlorate plume as depicted) and an attenuation rate for perchlorate similar to the rate observed for 18WW08 is achieved (~0.5 per year), allows perchlorate to attenuate to 72 µg/L in approximately seven (7) years. Similarly, for TCE, if an initial concentration outside the slurry wall of 20 µg/L (note that the slurry wall designed to capture perchlorate plume will encompass the entire TCE plume) and an attenuation rate similar to that observed for MW-8 (0.11 per year) were assumed, TCE would achieve the MCL in 12.5 years. Therefore, the time frame is estimated to be < 20 years to achieve cleanup goals outside the containment.

Since use of groundwater as a water supply is unlikely based on future land use at LHAAP-18/24, the time frame to achieve groundwater ARARs is considered acceptable. Based on the risk assessment (Jacobs, 2002) and surface water sampling results, groundwater contamination has not led to unacceptable risk from surface water.

6.2.3.2.2 Location-Specific ARARs

No location-specific were identified for LHAAP-18/24.

6.2.3.2.3 Action-Specific ARARs

Activities that would be conducted under this alternative would comply with all action-specific ARARs. Extraction of groundwater will be treated and discharged in accordance with Section 402 of the CWA.

The slurry wall and improved soil cover/drainage features would be constructed in compliance with all safety and transportation requirements. Runoff controls would be important during slurry wall construction. All runoff requirements would be met to protect Harrison Bayou. Construction at the western corner of the site would be implemented in compliance with flood plain management requirements. Removed soil will require characterization to determine disposal options and soil classification. All off-site disposal activities will comply with waste regulations and will be conducted using Department of Transportation permitted trucks. Storage of soil will meet storage requirements of hazardous waste as necessary. Unimpacted soil might be considered for reuse to construct the soil cover and improve drainage based on soil characteristics.

6.2.3.2.4 Non-ARAR Procedural Considerations

Certain activities that would be conducted under this alternative are similar to current activities of groundwater extraction, treatment monitoring, and discharge and would comply with all procedural considerations described in **Table 3-3**. The majority of the slurry wall will be placed in areas that already been disturbed, although there will be areas near Harrison Bayou that have not been previously disturbed. However, no impacts to archeological resources or threatened and endangered species are anticipated. Compliance with the substantive requirements with waste generation (soil cuttings), temporary storage, characterization, and off-site disposal are being carried out at this site and will be complied with during implementation of the remedy.

6.2.3.3 Long-Term Effectiveness and Permanence

6.2.3.3.1 Magnitude of Residual Risk

The risks from exposure to soil are already within the target risk range and below an HI of 1 for a hypothetical future maintenance worker.

The implementation of LUCs under this alternative would prevent direct contact by human receptors with the groundwater at LHAAP-18/24, thus minimizing the potential risk posed by groundwater contamination. Extraction of groundwater will result in continuous reduction in contaminant mass and mobility yielding reduction in overall risk to human health.

The occurrence of NA as determined in areas outside the containment to the northwest and southwest will continue to reduce risk after slurry wall installation. Further, groundwater is currently not used and is unlikely to be used in the future due to 1) the low yield expected from thin discontinuous sand lenses, 2) the proposed future land use, and 3) implementation of groundwater use restrictions.

6.2.3.3.2 Adequacy and Reliability of Controls

The implementation of LUCs would protect potential human receptors from exposure to contaminated groundwater at LHAAP-18/24 and ensure that site use is consistent with the hypothetical future maintenance worker scenario.

The adequacy and reliability of the slurry wall will depend on the quality of construction of the slurry wall and on maintaining a small head difference between the inside and outside the slurry wall. Since the wall will be placed in areas with very low concentrations of CoCs, the potential effect of CoCs on the wall integrity and effectiveness should be immaterial. The soil capping portion of this alternative will depend on maintenance of an adequate soil cover thickness and drainage features in the southeastern area of the site. The reliability of LUCs would depend on the long-term maintenance of the controls. Maintenance of the LUCs to restrict access to groundwater would be required indefinitely because contamination within the slurry wall would not be treated, although reduced groundwater extraction would be continued. Because the future use of the site is by a federal agency as a refuge, LUCs are highly effective. Periodic maintenance and Five-Year Reviews will ensure that the restrictions are enforced and remain effective. The Five-Year Reviews might indicate the need for components of this alternative to be maintained, modified, or replaced.

6.2.3.4 Reduction of Toxicity, Mobility, or Volume through Treatment

While this alternative is built around containment, the alternative includes two elements that will utilize treatment to reduce the toxicity, mobility, and volume of the contaminants in the LHAAP-18/24 groundwater:

- Operation of the groundwater extraction and treatment system as required to maintain an inward hydraulic gradient
- NA mechanisms in areas outside the slurry wall and Wilcox Formation

These two components satisfy the CERCLA statutory preference for remedial actions that permanently reduce contaminant toxicity, mobility, or volume through treatment. The reductions would be verified through monitoring, although the rate of mass reduction would be slower than for other alternatives.

The major element of the alternative, slurry wall containment, would reduce the mobility of the contamination, but would do so without treatment. A reservoir of contamination would remain on the site within the slurry wall.

6.2.3.5 Short-Term Effectiveness

6.2.3.5.1 Protection of the Community during Remedial Action

This alternative is protective of the surrounding community during remedy implementation primarily because all activities would occur on site with some disturbance of contaminated material. Truck traffic for equipment and materials, including the delivery of slurry wall materials and borrow soil (for improving soil cover and drainage at the site) would occur. Management of excavated soil will also result in using trucks to take the soil off-site for disposal. Increased road traffic will be a concern to the community and a traffic plan will be developed

and communicated to the community and traffic coordinated with local authorities as needed. During remediation activities at LHAAP-18/24, control of surface runoff would be important to avoid releases of contamination to adjacent surface water bodies.

Groundwater treatment is also an on-going operation and does not pose hazards to the community as determined via monitoring air and water.

6.2.3.5.2 Protection of the Workers during Remedial Action

Some short-term risks to human health or the environment would exist during implementation of this alternative. The slurry wall construction activities have the potential for transportation or construction accidents. Additionally, this alternative will involve potential short-term risks to workers associated with the operation of heavy equipment and potential exposure to decontamination fluids, contaminated groundwater, and possibly contaminated soil. Proper implementation of a comprehensive health and safety program should minimize risks associated with this alternative.

6.2.3.5.3 Short-Term Environmental Effects

Minor clearing and grubbing at LHAAP-18/24 would be required to improve soil cover, improve drainage features, and construct the slurry wall. Since the majority of the areas have been cleared in the past, it is unlikely that there are any sensitive species that would be impacted. If any sensitive areas are found, the appropriate regulation will be followed. Stormwater and drainage will be controlled to minimize loss of dredged material to the environment. The implementation of proper engineering controls will minimize the risk of environmental impacts.

6.2.3.5.4 Duration of Remedial Activities

The anticipated duration of the proposed construction activities, including mobilization/ demobilization, site preparation, soil placement, slurry wall construction, and site restoration is 15 months.

After construction of the slurry wall, monitoring would be implemented to demonstrate that VOCs and perchlorate remaining outside the slurry wall are attenuated by natural processes. NA of perchlorate and VOCs in the groundwater outside the slurry wall and within the Wilcox Formation will be monitored to demonstrate that the remedy is successfully operational.

Following demonstration of successful operation, LTM, consisting of LUCs and groundwater monitoring would be implemented semi-annually for two years, annually until the first Five-Year Review, two events two years apart, followed by two events every five years. After 20 years attainment of cleanup levels outside the containment barrier will occur and monitoring would not need to be performed thereafter. The amount of time needed to achieve cleanup levels outside the slurry wall in groundwater and within the Wilcox Formation would depend on the effectiveness of NA which determined cleanup to be achieved within 20 years. However, inside the slurry wall in the shallow zone there is no estimate for duration but will exceed several hundred years.

6.2.3.6 Implementability

6.2.3.6.1 Technical Feasibility

All components of this alternative are readily constructed and maintained. Slurry walls have been constructed at numerous sites with similar hydrogeology. The confining clay layer may need to be improved in some locations (e.g., west corner of the site). The ongoing operation of the existing groundwater extraction and treatment system demonstrates this capability. All equipment, services and materials are readily available to conduct the activities for this alternative.

A 2-year study will be conducted to determine how well the soil cover is working to reduce infiltration and how much groundwater extraction would be required to maintain an inward and upward gradient within the slurry wall. Availability of monitoring wells and instruments to measure rain amounts and gauge groundwater levels are readily available and implementable. Modifications of extraction rates and extraction locations will be conducted to optimize groundwater extraction to maintain desired gradients.

6.2.3.6.2 Administrative Feasibility

All actions under this alternative would be implemented on the site and thus do not require permits, though substantive provisions of permits that would otherwise be required are considered to be ARARs such as discharge of treated water to surface water meeting the established discharge limits. By agreement (i.e., the FFA), the U.S. Army shall submit to the USEPA and TCEQ a Responsiveness Summary and ROD. Following consideration of any comments by TCEQ, the ROD will be finalized jointly by the U.S. Army and USEPA. By addressing the identified ARARs in the ROD and subsequent documents, it is anticipated that the alternative would adequately address all administrative barriers.

LUCs, although administratively implementable, would require the development of an implementation plan as part of the remedial design, and internal notices to relevant regulatory offices of the existence of the LUCs. Approval by the USEPA and the State of Texas is required prior to the significant modification or termination of a LUC, implementation actions, or modification of land-use by the U.S. Army. The U.S. Army must also seek concurrence from the USEPA and the State of Texas prior to any action that may disrupt the effectiveness of the LUCs or any action that may alter or negate the need for LUCs.

Technology and skilled labor and equipment are available to implement this remedy including equipment and material for slurry wall construction. Technology, skilled labor, equipment, and material are available to operate and maintain the GWTP or to design, construct, and operate a new GWTP. Labor, tools, and methods are established for monitoring groundwater and air, as necessary.

6.2.3.7 Cost

The total net present value cost of Alternative 3 is approximately $18.65 million. The details of the cost estimates for all of the alternatives are presented in **Appendix D**. This represents the 30-year cost.

6.2.3.7.1 Direct Capital Cost

The net present value capital cost is estimated at $6.41 million. Capital costs include recapitalization of a new GWTP, major replacement every five years on year 10 for the lifecycle of the GWTP, and construction of the slurry wall and soil cover. The capital cost also includes activities associated with LUCs and the work plan, regulatory documents, and a closure report.

6.2.3.7.2 O&M Cost

The net present value O&M cost is estimated at approximately $12.24 million. The O&M cost includes operation of the reduced groundwater extraction and treatment system, reduced monitoring for performance, conducting the two year water balance study, and LUCs surveillance to verify continued industrial use. The LTM would support the required CERCLA Five-Year Reviews.

6.2.4 Alternative 4 –Enhanced Groundwater Extraction Inside Containment and Treatment, LUC, Enhanced ISB Inside & Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, and Surfactant Enhanced DNAPL Removal

This alternative consists of the following major components:

- Continued use of the existing groundwater extraction system with enhancements (reactivate two existing ICTs) until CoC concentrations are low enough that MNA can address remaining contamination within the containment area.
- Replacement of the existing GWTP with a new GWTP with the option to treat for 1,4-dioxane.
- Excavation of unsaturated soil exceeding groundwater protection standard (GWP-Ind).
- Excavation of unsaturated soil exceeding groundwater protection-industrial MSC (GWP-Ind). The estimated cost to excavate soil beneath the UEP is included in this alternative, and could be implemented in the future (e.g., depending on the results of the Five-Year Review of the groundwater remedy).
- Implementation of ISB of shallow zone groundwater outside the containment area at several locations; in the Wilcox Formation at three locations, and inside the containment at five locations.
- Implementation of surfactant flushing for removal of DNAPL in two distinct areas inside the containment area at the site.
- Maintenance of existing cap over the former UEP.
- Long-term LUCs to restrict and monitor groundwater use at the site.

6.2.4.1 Overall Protection of Human Health and the Environment

6.2.4.1.1 Protection of Human Health

Existing soil concentrations are protective of a hypothetical future maintenance worker, but existing groundwater concentrations pose a potential risk.

This alternative would achieve the RAOs for LHAAP-18/24. Implementation of the LUCs would prevent human access and exposure to groundwater that poses an unacceptable risk to human health until the remedy achieves the RAOs. The LUCs would include land use notification at the Harrison County courthouse and periodic surveillance of LHAAP-18/24 to ensure that use restrictions are not being violated. The U.S. Army would include the notice with any transfer letter to the USFWS for the intended future use as a national wildlife refuge. If transferred out of U.S. government control, deed restrictions would be placed on the property to prohibit or restrict property uses that may result in exposure to groundwater (e.g., drinking water well installation).

With enhanced groundwater extraction inside the containment, implementation of ISB on three (3) sides outside the containment, in the Wilcox Formation, and inside the containment in five (5) areas, removal of potential unsaturated source soils, and remediation of secondary source areas in the saturated soil inside the containment area in two distinct areas (former UEP and former ACD), this alternative should accelerate the process of achieving the RAOs. No reliance on NA is proposed for this alternative. Since NA is occurring at the site, its use as part of the remedy is inevitable. NA inside the containment is a feasible option to polish the residual CoCs remaining after groundwater extraction and ISB implementation are completed.

Groundwater use restrictions would remain in place until groundwater extraction and eventually NA reduces contaminant levels inside and outside the containment and in the Wilcox Formation to allow unrestricted use and unlimited exposure.

A monitoring program that would track the continual attenuation of the groundwater CoCs and verify that contamination is not reaching Harrison Bayou will be implemented. The LTM program would provide information to support Five-Year Reviews and the termination of the remedy when cleanup levels have been met.

Because MNA is not currently a viable alternative throughout the entire containment area, the enhanced groundwater extraction and treatment system would continue to be operated to prevent migration of CoCs from the containment area and reduce the concentrations of those CoCs over time inside and outside the containment. Over the long term, extraction and treatment would eventually achieve concentrations throughout the containment area and outside the containment area that could be addressed via NA. At that point, the extraction and treatment system would be shut down.

6.2.4.1.2 Protection of the Environment

Alternative 4 would adequately protect the environment. The Installation-Wide Baseline Ecological Risk Assessment did not identify potential risk to ecological receptors at LHAAP-18/24 and the BERA Addendum completed in 2014 (AGEISS, Inc., July 8, 2014) did not change the conclusion of the 2007 BERA. Should there have been any ecological risk, it would have been expressed by this point in time.

This alternative includes removal of unsaturated soil and residual DNAPL sources, thus reducing or eliminating the threat of additional impact to groundwater. The alternative also prevents groundwater from impacting surface water, thus providing protection from exposure to the environmental receptors.

6.2.4.2 Compliance with ARARs

6.2.4.2.1 Chemical-Specific ARARs

This alternative would achieve the cleanup levels for groundwater contaminants that exceed their respective ARARs since the CoCs are being removed by the enhanced groundwater extraction and treatment system, surfactant flushing system, and ISB from within the containment and further remediated by ISB outside the containment. The estimated restoration time frames for this alternative are shorter than Alternative 2 or 3. For Alternative 4, it is expected that the extraction and treatment system will continue to operate for a duration exceeding 30 years to extract the soluble and adsorbed mass from within the containment that is not treated with surfactant flushing or enhanced ISB. This time frame is estimated from attenuation rates occurring in existing shallow wells inside the containment. This time frame is driven by the limitation associated with dissolution of adsorbed mass into the groundwater phase and migration to extraction points. With DNAPL source removed, it is possible that a quicker decrease in CoC concentrations in certain areas that are currently influenced by DNAPL could occur. Additionally, as certain areas are remediated and data indicate that CoC migration is diminishing, certain extraction points could be turned off.

The duration to achieve RAOs for groundwater outside the containment area in association with ISB will be short (3-5 years) but will be limited to the areas influenced by the ISB biobarriers. Enough substrate will be added to last for two years for each application. Therefore, the coverage area would include a two year transport distance.

Since use of groundwater as a water supply is unlikely based on future land use at LHAAP-18/24, the time frame to achieve groundwater ARARs could be considered acceptable. Based on the risk assessment (Jacobs, 2002) and surface water sampling results, groundwater contamination has not led to unacceptable risk from surface water.

6.2.4.2.2 Location-Specific ARARs

No location-specific were identified for LHAAP-18/24.

6.2.4.2.3 Action-Specific ARARs

Activities that would be conducted under this alternative would comply with all action-specific ARARs. Extraction of groundwater will be treated and discharged in accordance with Section 402 of the CWA. ISB has been implemented at LHAAP previously and does not result in generating waste or air emissions. It typically is conducted using direct push tools to inject the substrate into the groundwater. The substrate and nutrients are food grade. Bacterial formulations have been in use for some time and have been proven to be benign to the environment. Surfactant use in groundwater has been implemented previously and surfactants are typically non-toxic biodegradable in nature. Soil excavation could result in particulate emissions that would be controlled by wetting excavation areas and conducting air monitoring with established

action levels. Stormwater best management practices would be developed and implemented. Excavated soils and soil cuttings from well installation will be characterized before disposal, stored in appropriate containers, and characterized for disposal in a protective landfill suitable to the class of waste. The wells will be constructed in accordance to established industry standards.

6.2.4.2.4 Non-ARAR Procedural Considerations

Activities that would be conducted under this alternative are similar to current activities of groundwater extraction, treatment monitoring, and discharge and would comply with all procedural considerations described in **Table 3-3**. ISB source area remediation, and soil excavation will be implemented in areas that have already been disturbed. No activities would take place in sensitive environments such as wetlands, and no impacts to archeological resources or threatened and endangered species are anticipated. Compliance with the substantive requirements with waste generation, temporary storage, characterization, and off-site disposal are being carried out at this site and will be complied with during implementation of the remedy.

6.2.4.3 Long-Term Effectiveness and Permanence

6.2.4.3.1 Magnitude of Residual Risk

The risks from exposure to soil are already within the target risk range and below an HI of 1 for a hypothetical future maintenance worker.

The implementation of LUCs under this alternative would prevent direct contact by human receptors with the groundwater at LHAAP-18/24, thus minimizing the potential risk posed by groundwater contamination. Extraction of groundwater will result in continuous reduction in contaminant mass and mobility yielding reduction in overall risk to human health. Implementation of residual DNAPL source remediation, soil excavation, and ISB will also result in reduction in CoC mass and mobility, reducing overall risk to human health. Once the RAOs are achieved, complete reduction of risk to human health will be attained.

The occurrence of NA as determined in areas inside (e.g., presence of daughter TCE products) and outside the containment to the northwest and southwest will continue to reduce risk during and after active remediation ceases. Furthermore, groundwater is currently not used and is unlikely to be used in the future due to 1) the low yield expected from thin discontinuous sand lenses, 2) the proposed future land use, and 3) implementation of groundwater use restrictions.

6.2.4.3.2 Adequacy and Reliability of Controls

The implementation of LUCs would protect potential human receptors from exposure to contaminated groundwater at LHAAP-18/24 and ensure that site use is consistent with the hypothetical future maintenance worker scenario. The adequacy and reliability of groundwater extraction and treatment system would depend on proper maintenance and operation. The system would be operated until such time as CoC concentrations are suitable for cessation of operation. The reliability of LUCs would depend on the long-term maintenance of the controls. Maintenance of the LUCs to restrict access to groundwater, would be required until cleanup levels are achieved. Because the future use of the site is by a federal agency as a refuge, LUCs are highly effective. Periodic maintenance and Five-Year Reviews will ensure that the

restrictions are enforced and remain effective. The Five-Year Reviews might indicate the need for components of this alternative to be maintained, modified, or replaced.

ISB for reduction of perchlorate and VOCs in shallow groundwater inside and outside the containment provides a permanent remedy by complete destruction of the CoCs. ISB will be implemented two times to ensure that any rebound that may occur or areas that are not treated receive additional treatment. Because the major source of CoCs located outside the containment is sourced from groundwater migration, ISB will be effective in reducing the contaminants and little to no rebound is expected. No maintenance is required between ISB applications.

DNAPL source area removal by surfactant flushing has been implemented on several sites and results in mobilizing DNAPL by solubilization followed by dual phase extraction (vapor and liquid forms) where the vapor phase is treated on site and the liquid phase is disposed off-site. Up to 90% removal of source material would be expected to be removed with this technology, although treatability testing to provide proof of concept is recommended. The presence of low K zones with residual DNAPL will hinder the effectiveness of this technology. The residual surfactant not removed is biodegradable and would result in enhanced is situ bioremediation over time to achieve complete cleanup. Follow up ISB in this area would adequately polish residual VOCs and remediate perchlorate from this area.

Soil excavation and disposal is a very well established process and should completely remove residual CoCs in the unsaturated soil.

6.2.4.4 Reduction of Toxicity, Mobility, or Volume through Treatment

This alternative has five elements that will reduce the toxicity, mobility, and volume of the contaminants in the LHAAP-18/24 groundwater:

- Operation of an enhanced groundwater extraction and treatment system to extract groundwater from within the containment area
- Surfactant flushing of saturated source soil to mobilize and extract DNAPL
- Implementation of ISB in shallow zone groundwater inside and outside the containment and in the Wilcox aquifer
- Excavation of unsaturated source soil
- NA mechanisms including biodegradation (while this is not relied on as a main remedial action, its natural occurrence and benefits are inevitable)

These components satisfy the CERCLA statutory preference for remedial actions that permanently reduce contaminant toxicity, mobility, or volume through treatment. The reductions would be verified through monitoring.

6.2.4.5 Short-Term Effectiveness

6.2.4.5.1 Protection of the Community during Remedial Action

This alternative is protective of the surrounding community during remedy implementation primarily because all activities would occur on site with very little disturbance of contaminated material. ISB has been implemented at LHAAP previously and implementation at LHAAP-18/24

creates little disturbance as the majority of the process is conducted below ground. Vehicular traffic for equipment and materials delivery for in situ treatment would occur. If a spill occurs, which contains food grade substrate, which is harmless to the community, could be contained and should not impact the surrounding communities. Vehicular traffic associated with soil excavation and disposal would also be of concern and plans to minimize impacts will be taken. Implementation of surfactant flushing also occurs primarily in situ until the fluid is extracted at such time potential emissions could occur but the impact on the community would be minimal. Air monitoring would be conducted to ascertain protective levels are not exceeded.

Groundwater extraction and treatment is also an on-going operation and does not pose hazards to the community as determined via monitoring air and water.

6.2.4.5.2 Protection of the Workers during Remedial Action

Some short-term risks to human health or the environment would exist during implementation of this alternative. ISB implementation using a direct push tool, soil excavation, surfactant flushing, the operation of the GWTP, and groundwater sampling activities might expose workers to contaminants in soil and groundwater. Exposure to heavy equipment is also possible. Well installation and trenching activities for pipelines and the operation of the GWTP might expose workers to contaminants in soil and groundwater. Proper implementation of a comprehensive health and safety program would minimize risks to workers associated with this alternative. Many of these activities have been implemented and some continue to be implemented without adverse effects on site workers.

6.2.4.5.3 Short-Term Environmental Effects

Minor clearing and grubbing at LHAAP-18/24 would be required to maintain access to monitoring wells or for access of DPT equipment for ISB implementation; however, since the majority of these areas have been cleared in the past, it is unlikely that there are any sensitive species that would be impacted. If any sensitive areas were found, the appropriate regulation would be followed. The implementation of proper engineering controls would minimize the risk of environmental impacts.

6.2.4.5.4 Duration of Remedial Activities

The anticipated duration of this remedial alternative depends on the effectiveness of the surfactant flushing process, ISB, and the groundwater extraction and treatment system achieving reductions of CoCs concentrations in groundwater to below the cleanup levels. These levels of CoCs in the shallow groundwater are not expected to be achieved within the 30-year time frame established for analyzing the alternatives.

Perchlorate, metals and VOCs detected in the groundwater are expected to continue to attenuate by operation of the enhanced groundwater extraction and treatment system and by NA. Influent and effluent concentrations as well as selected monitoring wells would continue to be monitored as part of the operation of the groundwater extraction and treatment system. These monitored concentrations will demonstrate that the remedy is OPS.

Performing surfactant flushing to remove up to 90% of source material in saturated soil should decrease the longevity of this remedy significantly (e.g., from > 500 years to <100 years or less

inside the containment). The duration of this alternative remains long because dissolution of sorbed contaminants and the need to migrate to extraction points are limiting steps. Removal of source soil will have a minimal effect on longevity of this alternative.

LTM (consisting of LUCs surveillance and groundwater monitoring) would be implemented quarterly for the first two years, semiannually for the next three years, then annually for the next five years, and once every two years thereafter. For costing purposes, a 30-year monitoring program is assumed. Until cleanup levels are met, monitoring would be needed to determine trends in groundwater contamination levels and effectiveness of the remedial action.

Outside the containment area, the time frame to achieve RAOs will be shorter (5 to 10 years) because less mass is present in that area and the majority of the mass is associated with groundwater migration (i.e., present originally in the dissolved phase and easier to extract). Evaluation of performance of ISB outside the containment will be determined when data are collected.

The duration of implementation of soil removal is less than one month. The duration to conduct surfactant flushing would be over several months up to one year. Each ISB event is conducted over several weeks and collectively ISB will take several months to implement. Reactivation of ICT 6 and ICT 9 will take a few weeks to implement.

6.2.4.6 Implementability

6.2.4.6.1 Technical Feasibility

All components of this alternative are readily implementable. ISB and associated equipment and reactivation of ICTs have been previously implemented at this site or other sites at LHAAP. ISB treatment has been used at sites throughout the U.S. for a number of years. Injection techniques and equipment are well developed. Implementation of ISB inside the containment could result in biofouling of extraction systems should electron donors migrate to the extraction points leading to potential problems at the GWTP. Surfactant flushing will require to be demonstrated at this site particularly related to site heterogeneity. Equipment and tools to implement this technology are readily available based on discussion with vendors (e.g., injection points, extraction points, vapor phase remediation). However, bench-scale and pilot-scale testing is recommended before full-scale design and implementation take place. The ongoing operation of the existing groundwater extraction and treatment system demonstrates this capability. All equipment, services and materials are readily available to conduct the activities for this alternative.

6.2.4.6.2 Administrative Feasibility

All actions under this alternative would be implemented on the site and thus do not require permits, though substantive provisions of permits that would otherwise be required are considered to be ARARs such as discharge of treated water to surface water meeting the established discharge limits and ISB and surfactant introduction meeting underground injection control requirements. By legal agreement (i.e., the FFA), the U.S. Army shall submit to the USEPA and TCEQ a Responsiveness Summary and ROD. Following consideration of any comments by TCEQ, the ROD will be finalized jointly by the U.S. Army and USEPA. By addressing the identified ARARs in the ROD and subsequent documents, it is anticipated that the alternative would adequately address all administrative barriers.

LUCs, although administratively implementable, would require the development of an implementation plan as part of the remedial design, and internal notices to relevant regulatory offices of the existence of the LUCs. Approval by the USEPA and the State of Texas is required prior to the significant modification or termination of a LUC, implementation actions, or modification of land-use by the U.S. Army. The U.S. Army must also seek concurrence from the USEPA and the State of Texas prior to any action that may disrupt the effectiveness of the LUCs or any action that may alter or negate the need for LUCs.

Technology and skilled labor and equipment are available to implement this remedy including equipment and material for ISB, surfactant flushing implementation, and to excavate, contain, transport, and dispose of excavated soil. Advance planning with specialty vendors should be conducted to avoid delays or market constraints for implementation of surfactant treatment. Technology, skilled labor, equipment, and material are available to operate and maintain the GWTP or to design, construct, and operate a new GWTP. Labor, tools, and methods are established for monitoring groundwater and air.

6.2.4.7 Cost

The total net present value cost of Alternative 4 is approximately $32.5 million. The details of the cost estimates for all of the alternatives are presented in **Appendix D**. This represents the 30-year cost.

6.2.4.7.1 Direct Capital Cost

The net present value capital cost is estimated at $13.11 million. Capital costs include recapitalization of a new GWTP, including contingency use of advanced oxidation technology for treating 1,4-dioxane, major replacement every five years beginning on year 10 for the lifecycle of the GWTP, excavation and disposal of unsaturated soils including the area under the UEP (assumed in year 6 for cost estimating purposes), implementation of surfactant flushing in the residual DNAPL areas, implementation of EISB, and reactivation of two ICTs. The capital cost also includes activities associated with LUCs and the work plan, regulatory documents, and a closure report.

6.2.4.7.2 O&M Cost

The net present value O&M cost is estimated at approximately $19.39 million. The O&M cost includes operation of the enhanced groundwater extraction and treatment system, monitoring for performance and MNA parameters in groundwater, and LUCs surveillance to verify continued industrial use. The LTM would support the required CERCLA Five-Year Reviews.

6.2.5 Alternative 5 –Enhanced Groundwater Extraction Inside Containment and Treatment, LUC, Enhanced ISB Inside and Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, Thermal DNAPL Removal

This alternative consists of the following major components:

- Continued use of the existing groundwater extraction system with enhancements (reactivate two existing ICTs) until CoC concentrations are low enough that MNA can address remaining contamination within the containment area.
- Replacement of the existing GWTP with a new GWTP with the option to treat for 1,4-dioxane.
- Excavation of unsaturated soil exceeding groundwater protection-industrial MSC (GWP-Ind). The estimated cost to excavate soil beneath the UEP is included in this alternative and could be implemented in the future (e.g., depending on the results of the Five-Year Review of the groundwater remedy).
- Implementation of ISB of shallow zone groundwater outside the containment area at several locations; in the Wilcox Formation at three locations, and inside the containment at five locations.
- Implementation of thermal desorption and removal of DNAPL in two distinct areas inside the containment area at the site.
- Maintenance of existing cap over the former UEP.
- Long-term LUCs to restrict and monitor groundwater use at the site.

6.2.5.1.1 Protection of Human Health

Existing soil concentrations are protective of a hypothetical future maintenance worker, but existing groundwater concentrations pose a potential risk.

This alternative would achieve the RAOs for LHAAP-18/24. Implementation of the LUCs would prevent human access and exposure to groundwater that poses an unacceptable risk to human health until the remedy achieves the RAOs. The LUCs would include land use notification at the Harrison County courthouse and periodic surveillance of LHAAP-18/24 to ensure that use restrictions are not being violated. The U.S. Army would include the notice with any transfer letter to the USFWS for the intended future use as a national wildlife refuge. If transferred out of U.S. government control, deed restrictions would be placed on the property to prohibit or restrict property uses that may result in exposure to groundwater (e.g., drinking water well installation).

With enhanced groundwater extraction inside the containment, implementation of ISB on three (3) sides outside the containment, in the Wilcox Formation, and inside the containment in five (5) areas, removal of potential unsaturated source soils, and remediation of secondary source areas in the saturated soil inside the containment area in two distinct areas (former UEP and former ACD), this alternative should accelerate the process of achieving the RAOs. No reliance on NA is proposed for this alternative. Since NA is occurring at the site, its use as part of the remedy is inevitable. NA inside the containment is a feasible option to polish the residual CoCs remaining after groundwater extraction operation and ISB implementation are completed.

Groundwater use restrictions would remain in place until groundwater extraction and eventually NA reduces contaminant levels inside and outside the containment and in the Wilcox Formation to allow unrestricted use and unlimited exposure.

A monitoring program that would track the continual attenuation of the groundwater CoCs and verify that contamination is not reaching Harrison Bayou will be implemented. The LTM program would provide information to support Five-Year Reviews and the termination of the remedy when cleanup levels have been met.

Because MNA is not currently a viable alternative throughout the entire containment area, the enhanced groundwater extraction and treatment system would continue to be operated to prevent migration of CoCs from the containment area and reduce the concentrations of those CoCs over time inside and outside the containment. Over the long term, extraction and treatment would eventually achieve concentrations throughout the containment area and outside the containment area that could be addressed via NA. At that point, the extraction and treatment system would be shut down.

6.2.5.1.2 Protection of the Environment

Alternative 5 would adequately protect the environment. The Installation-Wide Baseline Ecological Risk Assessment did not identify potential risk to ecological receptors at LHAAP-18/24 and the BERA Addendum completed in 2014 (AGEISS, Inc., July 8, 2014) did not change the conclusion of the 2007 BERA. Should there have been any ecological risk, it would have been expressed by this point in time.

This alternative includes removal of unsaturated soil and residual DNAPL sources, thus reducing or eliminating the threat of additional impact to groundwater. The alternative also prevents groundwater from impacting surface water, thus providing protection from exposure to the environmental receptors.

6.2.5.2 Compliance with ARARs

6.2.5.2.1 Chemical-Specific ARARs

This alternative would achieve the cleanup levels for groundwater contaminants that exceed their respective ARARs since the CoCs are being removed by the enhanced groundwater extraction and treatment system, thermal remediation system, and ISB from within the containment and further remediated by ISB outside the containment. The estimated restoration time frames for this alternative are shorter than other alternatives. For Alternative 5, it is expected that the extraction and treatment system will continue to operate for a duration up to 20 years to extract the soluble and adsorbed mass from within the containment that is not treated with thermal treatment and ISB.

This time frame is driven by the limitation associated with dissolution of adsorbed mass into the groundwater phase and migration to extraction points. With DNAPL source removed and ISB implemented in several high concentration areas at the site, it is possible that a quicker decrease in CoC concentrations could be witnessed. Additionally, as certain areas are remediated and data indicate that CoC migration is diminishing, certain extraction points could be turned off because the risk of CoC migration off-site would diminish significantly. Examples of those areas include the area adjacent to 109, MW-21, and 120.

The duration to achieve RAOs for groundwater outside the containment area in association with ISB will be short (3-5 years) but will be limited to the areas influenced by the ISB biobarriers.

Enough substrate will be added to last for two years for each application. Therefore, the coverage area would include a two year transport distance.

Since use of groundwater as a water supply is unlikely based on future land use at LHAAP-18/24, the time frame to achieve groundwater ARARs could be considered acceptable. Based on the risk assessment (Jacobs, 2002) and surface water sampling results, groundwater contamination has not led to unacceptable risk from surface water.

6.2.5.2.2 Location-Specific ARARs

No location-specific were identified for LHAAP-18/24.

6.2.5.2.3 Action-Specific ARARs

Activities that would be conducted under this alternative would comply with all action-specific ARARs. Extraction of groundwater will be treated and discharged in accordance with Section 402 of the CWA. ISB has been implemented at LHAAP previously and does not result in generating waste or air emissions. It typically is conducted using direct push tools to inject the substrate into the groundwater. The substrate and nutrients are food grade. Bacterial formulations have been in use for some time and have been proven to be benign to the environment. Thermal treatment is mostly conducted in situ although eventual extraction of vapors will be conducted and treated on site. Emission controls will be part of the process and any substantive requirements of permit by rule will be complied with. Soil excavation could result in particulate emissions that would be controlled by wetting excavation areas and conducting air monitoring with established action levels. Stormwater best management practices would be developed and implemented. Excavated soils and soil cuttings from well installation will be characterized before disposal, stored in appropriate containers, and characterized for disposal in a protective landfill suitable to the class of waste. The wells will be constructed in accordance to established industry standards.

6.2.5.2.4 Non-ARAR Procedural Considerations

Activities that would be conducted under this alternative are similar to current activities of groundwater extraction, treatment monitoring, and discharge and would comply with all procedural considerations described in **Table 3-3**. ISB source area remediation, and soil excavation will be implemented in areas that have already been disturbed. No activities would take place in sensitive environments such as wetlands, and no impacts to archeological resources or threatened and endangered species are anticipated. Compliance with the substantive requirements with waste generation, temporary storage, characterization, and off-site disposal are being carried out at this site and will be complied with during implementation of the remedy.

6.2.5.3 Long-Term Effectiveness and Permanence

6.2.5.3.1 Magnitude of Residual Risk

The risks from exposure to soil are already within the target risk range and below an HI of 1 for a hypothetical future maintenance worker.

The implementation of LUCs under this alternative would prevent direct contact by human receptors with the groundwater at LHAAP-18/24, thus minimizing the potential risk posed by

groundwater contamination. Extraction of groundwater will result in continuous reduction in contaminant mass and mobility yielding reduction in overall risk to human health. Implementation of residual DNAPL source remediation, soil excavation, and ISB will also result in reduction in CoC mass and mobility, reducing overall risk to human health. Once the RAOs are achieved, complete reduction of risk to human health will be attained.

The occurrence of NA as determined in areas inside (e.g., presence of daughter TCE products) and outside the containment to the northwest and southwest will continue to reduce risk during and after active remediation ceases. Furthermore, groundwater is currently not used and is unlikely to be used in the future due to 1) the low yield expected from thin discontinuous sand lenses, 2) the proposed future land use, and 3) implementation of groundwater use restrictions.

6.2.5.3.2 Adequacy and Reliability of Controls

The implementation of LUCs would protect potential human receptors from exposure to contaminated groundwater at LHAAP-18/24 and ensure that site use is consistent with the hypothetical future maintenance worker scenario. The adequacy and reliability of groundwater extraction and treatment system would depend on proper maintenance and operation of the GWTP. The system would be operated until such time as CoC concentrations are suitable for cessation of operation (i.e., risk of migration off-site is eliminated by a reduction in total mass in groundwater and source areas and natural attenuation is acting at a greater pace than contaminant migration). The reliability of LUCs would depend on the long-term maintenance of the controls. Maintenance of the LUCs to restrict access to groundwater, would be required until cleanup levels are achieved. Because the future use of the site is by a federal agency as a refuge, LUCs are highly effective. Periodic maintenance and Five-Year Reviews will ensure that the restrictions are enforced and remain effective. The Five-Year Reviews might indicate the need for components of this alternative to be maintained, modified, or replaced.

ISB for reduction of perchlorate and VOCs in shallow groundwater inside and outside the containment provides a permanent remedy by complete destruction of the CoCs. ISB will be implemented two times to ensure that any rebound that may occur or areas that are not treated receive additional treatment. Because the major source of CoCs located outside the containment is sourced from groundwater migration, ISB will be effective in reducing the contaminants and little to no rebound is expected. No maintenance is required between ISB applications.

DNAPL source area removal by thermal treatment has been implemented on many sites and results in volatilizing DNAPL followed by vapor phase extraction where the vapor phase is treated on site and liquid waste generate is disposed off-site. Construction and operation of the thermal treatment will be between 9 and 12 months. Greater than 99.9 percent removal of source material would be expected to be removed with this technology. Follow up ISB in this area would adequately polish residual VOCs and remediate perchlorate from this area.

Soil excavation and disposal is a very well established process and should completely remove residual CoCs in the unsaturated soil.

6.2.5.4 Reduction of Toxicity, Mobility, or Volume through Treatment

This alternative has five elements that will reduce the toxicity, mobility, and volume of the contaminants in the LHAAP-18/24 groundwater:

- Operation of an enhanced groundwater extraction and treatment system to extract groundwater from within the containment area
- Thermal treatment of saturated source soil to volatilize and extract DNAPL
- Implementation of ISB in shallow zone groundwater inside and outside the containment and in the Wilcox aquifer
- Excavation of unsaturated source soil
- NA mechanisms including biodegradation (while this is not relied on as a main remedial action, its natural occurrence and benefits are inevitable)

These components satisfy the CERCLA statutory preference for remedial actions that permanently reduce contaminant toxicity, mobility, or volume through treatment. The reductions would be verified through monitoring.

6.2.5.5 Short-Term Effectiveness

6.2.5.5.1 Protection of the Community during Remedial Action

This alternative is protective of the surrounding community during remedy implementation primarily because all activities would occur on site with very little disturbance of contaminated material. ISB has been implemented at LHAAP previously and implementation at LHAAP-18/24 creates little disturbance as the majority of the process is conducted below ground. Vehicular traffic for equipment and materials delivery for in situ treatment would occur. If a spill occurs, which contains food grade substrate, which is harmless to the community, could be contained and should not impact the surrounding communities. Vehicular traffic associated with soil excavation and disposal would also be of concern and plans to minimize impacts will be taken. Implementation of thermal treatment also occurs primarily in situ until the vapor is extracted at such time potential emissions could occur but vapor phase capture and treatment which is an integral part of the process will reduce any potential impact on the community. Air monitoring would be conducted to ascertain protective levels are not exceeded.

Groundwater treatment is also an on-going operation and does not pose hazards to the community as determined via monitoring air and water.

6.2.5.5.2 Protection of the Workers during Remedial Action

Some short-term risks to human health or the environment would exist during implementation of this alternative. ISB implementation using a direct push tool, soil excavation, thermal treatment, the operation of the GWTP, and groundwater sampling activities might expose workers to contaminants in soil and groundwater. Exposure to heavy equipment is also possible. Well installation and trenching activities for pipelines and the operation of the GWTP might expose workers to contaminants in soil and groundwater. Proper implementation of a comprehensive health and safety program would minimize risks to workers associated with this alternative. Many of these activities have been implemented and some continue to be implemented without adverse effects on site workers.

6.2.5.5.3 Short-Term Environmental Effects

Minor clearing and grubbing at LHAAP-18/24 would be required to maintain access to monitoring wells or for access of DPT equipment for ISB implementation; however, since the majority of these areas have been cleared in the past and are currently maintained, it is unlikely that there are any sensitive species that would be impacted. If any sensitive areas were found, the appropriate regulation would be followed. The implementation of proper engineering controls would minimize the risk of environmental impacts.

6.2.5.5.4 Duration of Remedial Activities

The anticipated duration of this remedial alternative depends on the effectiveness of the thermal treatment process, ISB, and the groundwater extraction and treatment system achieving reductions of CoCs concentrations in groundwater to below the cleanup levels. Implementing thermal treatment to remove greater than 99.9% of source material in saturated soil should decrease the longevity of this remedy significantly. ISB should be effective and achieve the cleanup levels in the areas of influence within five (5) years. Therefore, the cleanup levels in the shallow groundwater are expected to be achieved within 20 years at the majority of the site where treatment has occurred, allowing portions of the extraction system to be turned off within 10 years and completely discontinued by year 20. At that time any residual mass of CoCs will attenuate under “ISB enhanced” natural conditions.

Influent and effluent concentrations as well as selected monitoring wells would continue to be monitored as part of the operation of the groundwater extraction and treatment system. These monitored concentrations will demonstrate that the remedy is OPS.

LTM (consisting of LUCs surveillance and groundwater monitoring) would be implemented quarterly for the first two years, semiannually for the next three years, then annually for the next five years, and once every two years thereafter until year 20. After year 20, monitoring will consist of sampling once every 2 years until cleanup levels are achieved in all areas of the site. For costing purposes, a 30-year monitoring program is assumed. Until cleanup levels are met, monitoring would be needed to determine trends in groundwater contamination levels and effectiveness of the remedial action.

Outside the containment area, the time frame to achieve RAOs will be shorter (5 to 10 years) because less mass is present in that area and the majority of the mass is associated with groundwater migration (i.e., present originally in the dissolved phase and easier to extract). Evaluation of performance of ISB outside the containment will be determined when data are collected.

The duration of implementation of soil removal is less than one month. Thermal treatment would occur over several months up to one year. Each ISB event is conducted over several weeks and collectively ISB will take several months to implement. Reactivation of ICT 6 and ICT 9 will take a few weeks to implement.

6.2.5.6 Implementability

6.2.5.6.1 Technical Feasibility

All components of this alternative are readily implementable. ISB and associated equipment and reactivation of ICTs have been previously implemented at this site or other sites at LHAAP. ISB treatment has been used at sites throughout the U.S. for a number of years. Injection techniques and equipment are well developed. Implementation of ISB inside the containment could result in biofouling of extraction systems should electron donors migrate to the extraction points leading to potential problems at the GWTP. Thermal treatment has been demonstrated at other sites and the equipment and tools to implement this technology are readily available from specialty contractors (e.g., power sources, step downs, electrodes, extraction points, vapor phase remediation). The ongoing operation of the existing groundwater extraction and treatment system demonstrates this capability. All equipment, services and materials are readily available to conduct the activities for this alternative.

6.2.5.6.2 Administrative Feasibility

All actions under this alternative would be implemented on the site and thus do not require permits, though substantive provisions of permits that would otherwise be required are considered to be ARARs such as discharge of treated water to surface water meeting the established discharge limits and ISB and surfactant introduction meeting underground injection control requirements. By legal agreement (i.e., the FFA), the U.S. Army shall submit to the USEPA and TCEQ a Responsiveness Summary and ROD. Following consideration of any comments by TCEQ, the ROD will be finalized jointly by the U.S. Army and USEPA. By addressing the identified ARARs in the ROD and subsequent documents, it is anticipated that the alternative would adequately address all administrative barriers.

LUCs, although administratively implementable, would require the development of an implementation plan as part of the remedial design, and internal notices to relevant regulatory offices of the existence of the LUCs. Approval by the USEPA and the State of Texas is required prior to the significant modification or termination of a LUC, implementation actions, or modification of land-use by the U.S. Army. The U.S. Army must also seek concurrence from the USEPA and the State of Texas prior to any action that may disrupt the effectiveness of the LUCs or any action that may alter or negate the need for LUCs.

Technology and skilled labor and equipment are available to implement this remedy including equipment and material for ISB, thermal treatment implementation, and to excavate, contain, transport, and dispose of excavated soil. Advance planning with specialty vendors should be conducted to avoid delays or market constraints for implementation of thermal treatment. Technology, skilled labor, equipment, and material are available to operate and maintain the GWTP or to design, construct, and operate a new GWTP. Labor, tools, and methods are established for monitoring groundwater and air.

6.2.5.7 Cost

The total net present value cost of Alternative 5 is approximately $32.67 million. The details of the cost estimates for all of the alternatives are presented in **Appendix D**. This represents the 30-year cost.

6.2.5.7.1 Direct Capital Cost

The net present value capital cost is estimated at $19.52 million. Capital costs include recapitalization of a new GWTP, including contingency use of advanced oxidation technology for treating 1,4-doxane, major replacement every five years on year 10 for the lifecycle of the GWTP (20 years), excavation and disposal of unsaturated soils including the area under the UEP (assumed in year 6 for cost estimating purposes), implementation of thermal treatment within the residual DNAPL area, implementation of EISB, and reactivation of two ICTs. The capital cost also includes activities associated with LUCs and the work plan, regulatory documents, and a closure report.

6.2.5.7.2 O&M Cost

The net present value O&M cost is estimated at approximately $13.15 million. The O&M cost includes operation of the enhanced groundwater extraction and treatment system, monitoring for performance and MNA parameters in groundwater, and LUCs surveillance to verify continued industrial use. The LTM would support the required CERCLA Five-Year Reviews.

6.2.6 Alternative 6 –Enhanced Groundwater Extraction Inside Containment and Treatment, LUC, Enhanced ISB Inside and Outside Containment Area and in Wilcox Formation, Unsaturated Soil Excavation and Off-site Disposal, Enhanced DNAPL Remediation using ZVI

This alternative consists of the following major components:

- Continued use of the existing groundwater extraction system with enhancements (reactivate two existing ICTs) until CoC concentrations are low enough that MNA can address remaining contamination within the containment area.
- Replacement of the existing GWTP with a new GWTP with the contingency to treat for 1,4-dioxane.
- Excavation of unsaturated soil exceeding groundwater protection-industrial standard (GWP-Ind). The estimated cost to excavate soil beneath the UEP is included in this alternative, and could be implemented in the future (e.g., depending on the results of the Five-Year Review of the groundwater remedy).
- Implementation of ISB of shallow zone groundwater outside the containment area at several locations, in the Wilcox Formation at three locations, and inside the containment at five locations.
- Implementation of ZVI (micron-scale) for in situ treatment of DNAPL in two distinct areas inside the containment area at the site.
- Maintenance of existing cap over the former UEP.
- Long-term LUCs to restrict and monitor groundwater use at the site.

6.2.6.1 Overall Protection of Human Health and the Environment

6.2.6.1.1 Protection of Human Health

Existing soil concentrations are protective of a hypothetical future maintenance worker, but existing groundwater concentrations pose a potential risk.

This alternative would achieve the RAOs for LHAAP-18/24. Implementation of the LUCs would prevent human access and exposure to groundwater that poses an unacceptable risk to human health until the remedy achieves the RAOs. The LUCs would include land use notification at the Harrison County courthouse and periodic surveillance of LHAAP-18/24 to ensure that use restrictions are not being violated. The U.S. Army would include the notice with any transfer letter to the USFWS for the intended future use as a national wildlife refuge. If transferred out of U.S. government control, deed restrictions would be placed on the property to prohibit or restrict property uses that may result in exposure to groundwater (e.g., drinking water well installation).

With enhanced groundwater extraction inside the containment, implementation of ISB on three (3) sides outside the containment, in the Wilcox Formation, and inside the containment in five (5) areas, removal of potential unsaturated source soils, and remediation of secondary source areas in the saturated soil inside the containment area in two distinct areas (former UEP and former ACD), this alternative should accelerate the process of achieving the RAOs. No reliance on NA is proposed for this alternative. Since NA is occurring at the site, its use as part of the remedy is inevitable. NA inside the containment is a feasible option to polish the residual CoCs remaining after groundwater extraction operation and ISB implementation are completed.

Groundwater use restrictions would remain in place until groundwater extraction and eventually NA reduces contaminant levels inside and outside the containment and in the Wilcox Formation to unrestricted use and unlimited exposure.

A monitoring program that would track the continual attenuation of the groundwater CoCs and verify that contamination is not reaching Harrison Bayou will be implemented. The LTM program would provide information to support Five-Year Reviews and the termination of the remedy when cleanup levels have been met.

Because MNA is not currently a viable alternative throughout the entire containment area, the enhanced groundwater extraction and treatment system would continue to be operated to prevent migration of CoCs from the containment area and reduce the concentrations of those CoCs over time inside and outside the containment. Over the long term, extraction and treatment would eventually achieve concentrations throughout the containment area and outside the containment area that could be addressed via NA. At that point, the extraction and treatment system would be shut down.

6.2.6.1.2 Protection of the Environment

Alternative 6 would adequately protect the environment. The Installation-Wide Baseline Ecological Risk Assessment did not identify potential risk to ecological receptors at LHAAP-18/24 and the BERA Addendum completed in 2014 (AGEISS, Inc., July 8, 2014) did not change the conclusion of the 2007 BERA. Should there have been any ecological risk, it would have been expressed by this point in time.

This alternative includes removal of unsaturated soil and residual DNAPL sources, thus reducing or eliminating the threat of additional impact to groundwater. The alternative also prevents groundwater from impacting surface water, thus providing protection from exposure to the environmental receptors.

6.2.6.2 Compliance with ARARs

6.2.6.2.1 Chemical-Specific ARARs

This alternative would achieve the cleanup levels for groundwater contaminants that exceed their respective ARARs since the CoCs are being removed by the enhanced groundwater extraction and treatment system, ZVI implementation, and ISB within the containment area and further remediated by ISB outside the containment area. The estimated restoration time frames for this alternative are shorter than Alternatives 2, 3, and 4 but likely longer than Alternative 5. For Alternative 6, it is expected that the extraction and treatment system will continue to operate for a duration up to 30 years to extract the soluble and adsorbed mass from within the containment that is not treated directly with ZVI and ISB.

This time frame is driven by the limitation associated with dissolution of adsorbed mass into the groundwater phase and migration to extraction points. With DNAPL source removed and ISB implemented in several high concentration areas at the site, it is possible that a quicker decrease in CoC concentrations could be witnessed. Additionally, as certain areas are remediated and data indicate that CoC migration is diminishing, certain extraction points could be turned off because the risk of CoC migration off-site would diminish significantly. Examples of those areas include the area adjacent to 109, MW-21, and 120.

The duration to achieve RAOs for groundwater outside the containment area in association with ISB will be short (3-5 years) but will be limited to the areas influenced by the ISB biobarriers. Enough substrate will be added to last for two years for each application. Therefore, the coverage area would include a two year transport distance.

Since use of groundwater as a water supply is unlikely based on future land use at LHAAP-18/24, the time frame to achieve groundwater ARARs could be considered acceptable. Based on the risk assessment (Jacobs, 2002) and surface water sampling results, groundwater contamination has not led to unacceptable risk from surface water.

6.2.6.2.2 Location-Specific ARARs

No location-specific were identified for LHAAP-18/24.

6.2.6.2.3 Action-Specific ARARs

Activities that would be conducted under this alternative would comply with all action-specific ARARs. Extraction of groundwater will be treated and discharged in accordance with Section 402 of the CWA. ISB has been implemented at LHAAP previously and does not result in generating waste or air emissions. It typically is conducted using direct push tools to inject the substrate into the groundwater. The substrate and nutrients are food grade. Bacterial formulations have been in use for some time and have been proven to be benign to the environment. ZVI implementation is similar to ISB, but an inorganic substrate will be applied with majority of remediation occurring in situ. Soil excavation could result in particulate emissions that would be

controlled by wetting excavation areas and conducting air monitoring with established action levels. Stormwater best management practices would be developed and implemented. Excavated soils and soil cuttings from well installation will be characterized before disposal, stored in appropriate containers, and characterized for disposal in a protective landfill suitable to the class of waste. The wells will be constructed in accordance to established industry standards.

6.2.6.2.4 Non-ARAR Procedural Considerations

Activities that would be conducted under this alternative are similar to current activities of groundwater extraction, treatment monitoring, and discharge and would comply with all procedural considerations described in **Table 3-3**. ISB source area remediation, and soil excavation will be implemented in areas that have already been disturbed. No activities would take place in sensitive environments such as wetlands, and no impacts to archeological resources or threatened and endangered species are anticipated. Compliance with the substantive requirements with waste generation, temporary storage, characterization, and off-site disposal are being carried out at this site and will be complied with during implementation of the remedy.

6.2.6.3 Long-Term Effectiveness and Permanence

6.2.6.3.1 Magnitude of Residual Risk

The risks from exposure to soil are already within the target risk range and below an HI of 1 for a hypothetical future maintenance worker.

The implementation of LUCs under this alternative would prevent direct contact by human receptors with the groundwater at LHAAP-18/24, thus minimizing the potential risk posed by groundwater contamination. Extraction of groundwater will result in continuous reduction in contaminant mass and mobility yielding reduction in overall risk to human health. Implementation of residual DNAPL source remediation, soil excavation, and ISB will also result in reduction in CoC mass and mobility, reducing overall risk to human health. Once the RAOs are achieved, complete reduction of risk to human health will be attained.

The occurrence of NA as determined in areas inside (e.g., presence of daughter TCE products) and outside the containment to the northwest and southwest will continue to reduce risk during and after active remediation ceases. Furthermore, groundwater is currently not used and is unlikely to be used in the future due to 1) the low yield expected from thin discontinuous sand lenses, 2) the proposed future land use, and 3) implementation of groundwater use restrictions.

6.2.6.3.2 Adequacy and Reliability of Controls

The implementation of LUCs would protect potential human receptors from exposure to contaminated groundwater at LHAAP-18/24 and ensure that site use is consistent with the hypothetical future maintenance worker scenario. The adequacy and reliability of groundwater extraction and treatment system would depend on proper maintenance and operation of the GWTP. The system would be operated until such time as CoC concentrations are suitable for cessation of operation (i.e., risk of migration off-site is eliminated by a reduction in total mass in groundwater and source areas and natural attenuation is acting at a greater pace than contaminant migration). The reliability of LUCs would depend on the long-term maintenance of the controls. Maintenance of the LUCs to restrict access to groundwater, would be required until cleanup

levels are achieved. Because the future use of the site is by a federal agency as a refuge, LUCs are highly effective. Periodic maintenance and Five-Year Reviews will ensure that the restrictions are enforced and remain effective. The Five-Year Reviews might indicate the need for components of this alternative to be maintained, modified, or replaced.

ISB for reduction of perchlorate and VOCs in shallow groundwater inside and outside the containment provides a permanent remedy by complete destruction of the CoCs. ISB will be implemented two times to ensure that any rebound that may occur or areas that are not treated receive additional treatment. Because the major source of CoCs located outside the containment is sourced from groundwater migration, ISB will be effective in reducing the contaminants and little to no rebound is expected. No maintenance is required between ISB applications.

DNAPL source area remediation by ZVI has been implemented on several sites and results in destruction of chlorinated VOCs in the DNAPL. Treatability study conducted on site material provided evidence of effectiveness of ZVI in treating TCE and to a lesser extent MC and perchlorate at the site. Application of ZVI is conducted via readily available tools. Greater than 99% destruction of TCE would be expected with lesser %age removal for MC and perchlorate. However, the ability to distribute injected ZVI into low K zones with high residual DNAPL may not be effective, and achieving results comparable to treatability study results is unlikely. Due to the difficulty in distributing the injected ZVI in low K zones, ZVI application is assumed to remove no more than 70% to 80% of the mass of VOCs per application. However, the creation of a very reducing condition in the subsurface creates the condition for effective natural biodegradation or enhanced ISB.

Soil excavation and disposal is a well-established process and should completely remove residual CoCs in the unsaturated soil.

6.2.6.4 Reduction of Toxicity, Mobility, or Volume through Treatment

This alternative has five elements that will reduce the toxicity, mobility, and volume of the contaminants in the LHAAP-18/24 groundwater:

- Operation of an enhanced groundwater extraction and treatment system to extract groundwater from within the containment area
- ZVI implementation in the saturated source soil to destroy DNAPL via abiotic means
- Implementation of ISB in shallow zone groundwater inside and outside the containment and in the Wilcox aquifer
- Excavation of unsaturated source soil
- NA mechanisms including biodegradation (while this is not relied on as a main remedial action, its natural occurrence and benefits are inevitable)

These components satisfy the CERCLA statutory preference for remedial actions that permanently reduce contaminant toxicity, mobility, or volume through treatment. The reductions would be verified through monitoring.

6.2.6.5 Short-Term Effectiveness

6.2.6.5.1 Protection of the Community during Remedial Action

This alternative is protective of the surrounding community during remedy implementation primarily because all activities would occur on site with very little disturbance of contaminated material. ISB has been implemented at LHAAP previously and implementation at LHAAP-18/24 creates little disturbance as the majority of the process is conducted below ground. Implementation of ZVI is very similar to ISB and remediation occurs in the subsurface. Vehicular traffic for equipment and materials delivery for in situ treatment would occur. If a spill occurs, which contains food grade substrate and iron, which is harmless to the community, could be contained and should not impact the surrounding communities. Vehicular traffic associated with soil excavation and disposal would also be of concern and plans to minimize impacts will be taken.

Groundwater treatment is also an on-going operation and does not pose hazards to the community as determined via monitoring air and water.

6.2.6.5.2 Protection of the Workers during Remedial Action

Some short-term risks to human health or the environment would exist during implementation of this alternative. ISB and ZVI implementation using a direct push tool, soil excavation, the operation of the GWTP, and groundwater sampling activities might expose workers to contaminants in soil and groundwater. Exposure to heavy equipment is also possible. Well installation and trenching activities for pipelines and the operation of the GWTP might expose workers to contaminants in soil and groundwater. Proper implementation of a comprehensive health and safety program would minimize risks to workers associated with this alternative. Many of these activities have been implemented and some continue to be implemented without adverse effects on site workers.

6.2.6.5.3 Short-Term Environmental Effects

Minor clearing and grubbing at LHAAP-18/24 would be required to maintain access to monitoring wells or for access of DPT equipment for ISB implementation; however, since the majority of these areas have been cleared in the past and are currently maintained, it is unlikely that there are any sensitive species that would be impacted. If any sensitive areas were found, the appropriate regulation would be followed. The implementation of proper engineering controls would minimize the risk of environmental impacts.

6.2.6.5.4 Duration of Remedial Activities

The anticipated duration of this remedial alternative depends on the effectiveness of ZVI and ISB implementation, and the groundwater extraction and treatment system achieving reductions of CoCs concentrations in groundwater to below the cleanup levels. Implementing ZVI to remove greater than 99% of TCE and a large %age of MC and perchlorate in saturated soil should decrease the longevity of this remedy significantly. However, due to the difficulty in distributing the injected ZVI in low K zones, ZVI application is assumed to remove no more than 70% to 80% of the mass of VOCs per application. ISB should be effective and achieve the cleanup levels in the areas of influence within five (5) years. Therefore, the cleanup levels in the shallow

groundwater are expected to be achieved within 30 years at the majority of the site where treatment has occurred, allowing portions of the extraction system to be turned off within 10 years and completely discontinued by year 30. At that time any residual mass of CoCs will attenuate under "ISB enhanced" natural conditions.

Influent and effluent concentrations as well as selected monitoring wells would continue to be monitored as part of the operation of the groundwater extraction and treatment system. These monitored concentrations will demonstrate that the remedy is OPS.

LTM (consisting of LUCs surveillance and groundwater monitoring) would be implemented quarterly for the first two years, semiannually for the next three years, then annually for the next five years, and once every two years thereafter until year 30. After year 30, monitoring will consist of sampling once every 5 years until cleanup levels are achieved in all areas of the site. For costing purposes, a 30-year monitoring program is assumed. Until cleanup levels are met, monitoring would be needed to determine trends in groundwater contamination levels and effectiveness of the remedial action.

Outside the containment area, the time frame to achieve RAOs will be shorter (5 to 10 years) because less mass is present in that area and the majority of the mass is associated with groundwater migration (i.e., present originally in the dissolved phase and easier to extract). Evaluation of performance of ISB outside the containment will be determined when data are collected.

The duration of implementation of soil removal is less than one month. ZVI implementation would occur over several months. Each ISB event is conducted over several weeks and collectively ISB will take several months to implement. Reactivation of ICT 6 and ICT 9 will take a few weeks to implement.

6.2.6.6 Implementability

6.2.6.6.1 Technical Feasibility

All components of this alternative are readily implementable. ZVI and ISB implementation and associated equipment and reactivation of ICTs have been previously implemented at this site or other sites at LHAAP. ISB treatment has been used at sites throughout the U.S. for a number of years. Injection techniques and equipment are well developed. Implementation of ISB inside the containment could result in biofouling of extraction systems should electron donors migrate to the extraction points leading to potential problems at the GWTP. The ongoing operation of the existing groundwater extraction and treatment system demonstrates this capability. All equipment, services and materials are readily available to conduct the activities for this alternative.

6.2.6.6.2 Administrative Feasibility

All actions under this alternative would be implemented on the site and thus do not require permits, though substantive provisions of permits that would otherwise be required are considered to be ARARs such as discharge of treated water to surface water meeting the established discharge limits and ZVI and ISB introduction meeting underground injection control requirements. By legal agreement (i.e., the FFA), the U.S. Army shall submit to the USEPA and

TCEQ a Responsiveness Summary and ROD. Following consideration of any comments by TCEQ, the ROD will be finalized jointly by the U.S. Army and USEPA. By addressing the identified ARARs in the ROD and subsequent documents, it is anticipated that the alternative would adequately address all administrative barriers.

LUCs, although administratively implementable, would require the development of an implementation plan as part of the remedial design, and internal notices to relevant regulatory offices of the existence of the LUCs. Approval by the USEPA and the State of Texas is required prior to the significant modification or termination of a LUC, implementation actions, or modification of land-use by the U.S. Army. The U.S. Army must also seek concurrence from the USEPA and the State of Texas prior to any action that may disrupt the effectiveness of the LUCs or any action that may alter or negate the need for LUCs.

Technology and skilled labor and equipment are available to implement this remedy including equipment and material for ZVI and ISB implementation. Advance planning with specialty vendors should be conducted to avoid delays or market constraints for acquisition of ZVI material. Technology, skilled labor, equipment, and material are available to operate and maintain the GWTP or to design, construct, and operate a new GWTP. Labor, tools, and methods are established for monitoring groundwater and air.

6.2.6.7 Cost

The total net present value cost of Alternative 6 is approximately $121.62 million. The details of the cost estimates for all of the alternatives are presented in **Appendix D**. This represents the 30-year cost.

6.2.6.7.1 Direct Capital Cost

The net present value capital cost is estimated at $102.23 million. Capital costs include cost of micro-scale ZVI, recapitalization of a new GWTP including contingency use of advance oxidation technology for treating 1,4-dioxane, major replacement every five years on year 10 for the lifecycle of the GWTP (20 years), excavation and disposal of unsaturated soils including the area under the UEP (assumed in year 6 for cost estimating purposes), implementation of EISB, and reactivation of two ICTs. The capital cost also includes activities associated with LUCs and the work plan, regulatory documents, and a closure report.

6.2.6.7.2 O&M Cost

The net present value O&M cost is estimated at approximately $19.39 million. The O&M cost includes operation of the enhanced groundwater extraction and treatment system, implementation of ZVI in the two identified source areas, monitoring for performance and MNA parameters in groundwater, and LUCs surveillance to verify continued industrial use. The LTM would support the required CERCLA Five-Year Reviews.

6.3 Comparative Analysis of Alternatives

6.3.1 Introduction

This section presents a comparative analysis of the remedial alternatives for LHAAP-18/24 according to the CERCLA evaluation criteria described in **Section 6.2**. This analysis is the

second stage of the detailed evaluation process and provides information that forms the basis for selecting a preferred remedy.

This comparative analysis considers two of the three criteria categories, the threshold criteria and primary balancing criteria. The threshold category contains two criteria that must be satisfied by the selected alternative:

- Overall protection of human health and the environment; and
- Compliance with ARARs.

These criteria are important because they reflect the key statutory mandates of CERCLA. If an alternative does not satisfy both of these criteria, it is not eligible to be selected.

The primary balancing category contains five criteria under which the relative advantages and disadvantages of the alternatives are compared to determine the most appropriate remedy. The five criteria are the following:

- Long-term effectiveness and permanence
- Reduction of toxicity, mobility, or volume through treatment
- Short-term effectiveness
- Implementability
- Cost

The comparison of these five criteria for the alternatives forms the basis of the comparative analysis. Together, they form the basis for determining the general feasibility of each alternative and for determining whether costs are proportional to the overall effectiveness.

The two modifying criteria, state and community acceptance, must be satisfied if the alternative is to be accepted. The modifying criteria of state and community acceptance are typically not evaluated until the public has had an opportunity to comment on the PP. Because specific alternatives have not been presented to the state and community, these two criteria are not formally compared within this FS.

A comparative analysis under the threshold and primary balancing criteria is presented in **Sections 6.3.2** and **6.3.3**, respectively, and is consistent with the format of the individual analysis of alternatives in **Section 6.2**.

6.3.2 Threshold Criteria

6.3.2.1 Overall Protection of Human Health and the Environment

The six alternatives provide varying levels of human health protection. Alternative 1, no action, does not achieve the RAOs and provides the least protection of all the alternatives; it provides no reduction in risks to human health and the environment because no measures would be implemented to eliminate potential exposure pathways for human exposure to the groundwater contamination or potential migration of CoCs from groundwater to surface water.

All five action alternatives protect human health and the environment. The action alternatives implement LUCs to prevent exposure to contaminated groundwater and continue operation of the

groundwater extraction and treatment system until monitoring data verifies that the contaminant plume originating within the containment area is stable and contained. Alternative 3, which relies the most heavily on containment and LUCs, does not provide the same degree of contaminant removal or treatment in groundwater as the other alternatives, but would be protective of human health because the LUCs would prevent human access to the contaminated groundwater. Alternative 3 does not prevent migration of CoCs from groundwater outside containment to surface water and it does not prevent migration of CoCs from soil sources in the unsaturated and saturated soil to groundwater. Alternatives 2, 4, 5, and 6 provide a similar level of overall protection and can eventually achieve the cleanup levels for the groundwater CoCs due to active remediation and continued operation of the groundwater treatment system for contaminant removal; however, the duration to achieve the cleanup levels vary.

6.3.2.2 Compliance with ARARs

Alternative 1 does not comply with chemical-specific ARARs for groundwater, unsaturated soils, or secondary source within the saturated soil because no remedial measures would be implemented.

Alternative 3 is not expected to return groundwater concentrations within the slurry wall to less than the cleanup levels, so it does not meet the return to beneficial use RAO within the slurry wall. Alternative 3 will require an ARAR waiver for the groundwater within the slurry wall.

Alternatives 2, 4, 5, and 6 comply with the chemical-specific ARARs for groundwater, unsaturated soil, and secondary groundwater source (residual DNAPL) because they prevent exposure to groundwater that exceeds ARARs and would eventually return groundwater and soil concentrations to less than cleanup levels.

All of the action alternatives would comply with the action-specific ARARs and any non-ARAR considerations.

6.3.3 Primary Balancing Criteria

6.3.3.1 Long-Term Effectiveness and Permanence

Alternative 1 would be the least effective and permanent in the long term because no contaminant removal or treatment would take place and no measures would be implemented to control exposure to risks posed by contaminated groundwater or the potential for contaminated groundwater to migrate to Harrison Bayou.

Alternative 2 offers a moderate degree of long-term effectiveness through operation of an enhanced groundwater extraction and treatment system, combined with unsaturated soil removal, residual DNAPL source removal, and LUCs implementation, which would minimize the potential risk posed by the contaminated groundwater. Reduction of the residual DNAPL source with groundwater extraction is not highly effective and therefore, the magnitude of residual risk will remain unacceptable.

Alternative 3 offers a degree of long-term effectiveness through physical containment of contaminated groundwater using a slurry wall and gradient control by pumping, combined with MNA to monitor effectiveness and LUCs to prevent groundwater use. Alternative 3 is designed to contain contaminated groundwater in place in perpetuity and would require a waiver of the

restoration RAO prior to implementation. This alternative is effective in containing the contaminants but not practical as operation of the GWTP will have to occur in perpetuity.

Alternative 4 offers a higher degree of long-term effectiveness compared to Alternatives 2 and 3 through surfactant flushing of residual DNAPL, ISB of groundwater inside and outside the containment and in the Wilcox Formation including as a polishing step for the residual DNAPL areas in the shallow zone, unsaturated soil excavation, enhanced groundwater extraction and treatment system, and LUCs implementation. Alternative 4 is likely to achieve groundwater cleanup levels in a shorter period of time than Alternative 2. However, the period of time remains long because the effectiveness of surfactant flushing of residual DNAPL in low K zones is uncertain due to the difficulty in reaching into the low K zones.

Alternative 5 offers the highest degree of long-term effectiveness through thermal remediation of VOCs in residual DNAPL saturated soil areas in groundwater, ISB of groundwater inside and outside the containment and in the Wilcox Formation including as a polishing step for the residual DNAPL areas in the shallow zone, unsaturated soil excavation, enhanced groundwater extraction and treatment system, and LUCs implementation. Alternative 5 will achieve groundwater cleanup levels in a shorter period of time than Alternatives 3 or 4 because 99.9% removal of VOCs from the residual DNAPL areas is possible.

Alternative 6 also offers a high degree of long-term effectiveness through application of ZVI to the residual DNAPL saturated soil areas, ISB of groundwater inside and outside the containment and in the Wilcox Formation including as a polishing step for the residual DNAPL areas in the shallow zone, unsaturated soil excavation, enhanced groundwater extraction and treatment, and LUCs implementation. Alternative 6 relies on effective distribution of injected ZVI to all impacted areas. However, the ability to distribute injected ZVI into low K zones with high residual DNAPL may not be effective, and achieving results comparable to the treatability study results of greater than 99% reduction of TCE and high percentage reduction of MC and perchlorate is unlikely.

Alternative 5 is expected to have the shortest duration to shutdown of the GWTP. Alternatives 4 and 6, while rapidly addressing CoCs in residual DNAPL areas, suffer from the difficulty of distributing the injected material to low K zones and may not be as effective as would be expected from a treatability test results where contact between the contaminants and the material is not limiting. Alternative 2 will not achieve the RAOs within an acceptable period of time (e.g., within 30 years). Alternative 3 would not reach cleanup levels within the slurry wall, and, due to the risk of containment failure, would be the least permanent remedy.

6.3.3.2 Reduction of Toxicity, Mobility, or Volume through Treatment

Alternative 1 does not employ treatment in groundwater and would not result in a reduction of toxicity, mobility, or volume of contaminants. All of the action alternatives provide some degree of reduction of toxicity, mobility or volume through treatment.

Alternative 2 provides a reduction in toxicity, mobility and volume via continued operation of an enhanced groundwater extraction and treatment system but the rate of reduction expected within the residual DNAPL areas will be slow.

Alternative 3 provides mobility reduction through the installation of a slurry wall and continued hydraulic control as needed. Reduction of volume through treatment is limited to NA

mechanisms of contaminants outside the slurry wall and ex situ treatment of extracted groundwater from within the containment area.

Alternative 4 provides faster permanent reduction in toxicity and volume of the groundwater contaminants than Alternatives 2, and 3. This is achieved through surfactant flushing of saturated source soil to remove DNAPL that may serve as a long-term source of groundwater contamination, excavation of unsaturated soil, and implementation of ISB in areas inside and outside the containment and within the Wilcox Formation. In addition to enhanced groundwater extraction, all the above technologies will result in a reduction in contaminant toxicity, mobility, and volume. However, reduction of mass of residual DNAPL via surfactant flushing is expected to be partial due to difficulty of surfactants to reach low K zones. NA mechanisms of contamination outside the containment area will continue to act to reduce contaminant mass.

Alternative 5 provides the greatest reduction in toxicity, mobility, and volume of the groundwater contaminants compared to the other alternatives. This is achieved through thermal treatment of saturated source soil to treat DNAPL that may serve as a long-term source of groundwater contamination, excavation of unsaturated soil, and implementation of ISB in areas inside and outside the containment and within the Wilcox Formation. In addition to enhanced groundwater extraction, this technology will result in a reduction in contaminant toxicity, mobility, and volume. NA mechanisms of contamination outside the containment area will continue to act to reduce contaminant mass.

Alternative 6 provides a high level of reduction in toxicity, mobility, and volume of the groundwater contaminants compared to the other alternatives but is expected to be less than that achieved by Alternative 5. Reduction of mass of residual DNAPL via ZVI injection is expected to be partial due to difficulty of ZVI to effectively reach low K zones. Excavation of unsaturated soil and implementation of ISB in areas inside and outside the containment and within the Wilcox Formation, in addition to enhanced groundwater extraction will result in a reduction in contaminant toxicity, mobility, and volume. NA mechanisms of contamination outside the containment area will continue to act to reduce contaminant mass.

6.3.3.3 Short-Term Effectiveness

Because Alternative 1 does not involve remedial measures, no short-term risk to workers, the community, or the environment would exist.

All of the action alternatives involve potential short-term risks to workers associated with exposure to contaminated groundwater, vapor (i.e., volatilized and extracted VOCs), from monitoring and/or operation of drilling/construction equipment.

Alternative 2 presents risks associated with drilling new extraction wells, trenching for placement of conduits, and potential exposure to contaminated groundwater or heavy equipment. Alternative 2 presents potential risks associated with soil excavation (particulate emissions, heavy equipment) and off-site disposal which represents a greater exposure potential to LHAAP-18/24 workers, a greater potential for runoff releases to the environment and the potential for off-site traffic accidents and impacts on communities between LHAAP and the disposal facility. Risks are also associated with handling of chemicals used for ISB, although these chemicals are typically food grade and not harmful. Use of application equipment can also present risk.

Alternative 3 involves risks associated with the heavier equipment used in slurry wall construction and with handling the bentonite slurry used in construction. Alternative 4 requires a large construction footprint and will result in disturbing a wide area along the path of construction which will have impact on the environment. Control of run-on and run-off would be critical to prevent cross-contamination of surface water. Risks associated with subsurface utilities are another concern for slurry wall installation.

Alternative 4 involves the same risks as Alternative 2 with the additional risks associated with surfactant flushing implementation which includes potential exposure to the surfactant and extracted fluids from the subsurface which would require surface handling, storage, treatment, and disposal.

Alternative 5 presents similar risks like Alternative 2 but has additional risks associated with implementation of thermal treatment technology which requires use of high voltage equipment and results in volatilization of VOCs that requires treatment at the ground surface.

Alternative 6 presents similar risks like Alternative 2 but with additional risk associated with use and handling of ZVI.

By planning the construction, excavation, and transportation activities in accordance with industry and OSHA codes and requirements, risks from contaminant exposure and construction operations would be controlled to acceptable levels. Dust control and sediment deposition into adjacent surface water bodies can be controlled during earthwork and construction activities. Erosion control measures would include surface grading; emplacement of silt fences; covering surfaces with straw, mulch, riprap, and/or geotextile fabrics. Following completion of all construction and excavation, disturbed areas would be regraded with clean backfill and revegetated with native grasses. Appropriate PPE would be required for remediation workers. Overall risk can be mitigated by developing a health and safety plan in compliance with OSHA requirements, communicating the hazards to involved parties, and providing the know-how and tools to mitigate those hazards.

6.3.3.4 Implementability

Administratively, all the action alternatives are implementable. However, Alternative 1, No Action, would involve shutting down the groundwater extraction system, which is assumed to be administratively unacceptable to the U.S. Army and to the regulatory agencies.

The action alternatives for groundwater are all technically implementable with varying degrees of difficulty.

Reactivation of existing ICTs for Alternatives 2, 4, 5, and 6 should be easy to implement as the tools and skilled resources are available. Similarly, implementation of additional extraction points for Alternative 2 should not pose any difficulties to drill the wells and connect the wells to the GWTP. ISB is specified for Alternatives 2, 4, 5, and 6. ISB has been implemented at other LHAAP sites and should not pose any difficulties to implement at LHAAP-18/24. Success of ISB was determined by conducting treatability testing and bioaugmentation at the laboratory scale. Treatability testing at the bench-scale and pilot-scale will also be required for surfactant remediation to select and optimize surfactant dose and provide proof of concept for Alternative 4 (i.e., loss of control for DNAPL migration, generation of adverse chemicals, and penetration effectiveness in low K zones). Thermal treatment (Alternative 5) does not require treatability

testing and its implementability hinges on the availability of power to supply the electrodes with sufficient power to heat the saturated soils. Considering that power reliability has been a concern at the GWTP, this would be an important design consideration for this technology. Implementation of ZVI for Alternative 6 faces similar implementability considerations such as ISB implementation.

Alternative 3 has two significant implementation issues:

- The slurry wall would need to key into the confining layer for the shallow zone.
- Any significant discontinuities in the confining layer would need to be addressed.

There are areas at LHAAP-18/24 where both issues exist. Technologies are available to address both issues, but it will be difficult to ensure the quality of containment throughout the system.

For Alternative 2, 4, 5, and 6 soil excavation would also require coordination between excavation, sampling, transportation and disposal. However, because the volumes are not large, resources are readily available to implement.

6.3.3.5 Cost

Cost estimates are used in the CERCLA FS process to eliminate those remedial alternatives that are significantly more expensive than competing alternatives without offering commensurate increases in performance or overall protection of human health or the environment. The cost estimates developed are preliminary estimates with an intended accuracy range of +50 to –30 percent. Final costs will depend on actual labor and material costs, actual site conditions, productivity, competitive market conditions, final scope, final schedule, final engineering design, and other variables.

The costs include both capital costs (including fixed-price remedial construction) and long-term O&M costs (post-remediation). Overall 30-year present value costs are developed for each alternative assuming a discount rate of 3.0 percent. Total present value costs for each alternative are presented in **Appendix D** and a summary is presented below. It should be noted that some alternatives have extensive capital costs but could result in a serious reduction in the alternative lifecycle to achieve the RAOs (e.g., less than 30 years). Other alternatives that do not rely on intensive upfront remediation technologies have a very long remediation lifecycle (i.e., well beyond 30 years) that would outweigh the alternatives with high capital cost. Because cost determination was limited to 30 years per CERCLA requirements, the alternatives with high capital costs (e.g., Alternatives 5 and 6) appear to be as or more expensive on a 30-year basis than alternatives with low capital costs but long lifecycle duration (e.g., Alternatives 2 and 3).

The progression of total present value costs from the least expensive alternative to the most expensive alternative is as follows: Alternative 1, Alternative 3, Alternative 4, Alternative 5, Alternative 2, and Alternative 6. There are no costs associated with Alternative 1 because no remedial activities would be conducted. Alternative 6 has highest capital costs due to the high cost of ZVI, but lower O&M costs than all other alternatives with the exception of Alternatives 3 and 5. Alternative 5 has an O&M cost over 20 years after which the GWTP and extraction would be shut down. Alternative 5 has a higher capital cost associated with thermal treatment compared to Alternatives 2, 3, and 4. Alternatives 2, 3, and 4 have the lowest capital costs of the active remedial alternatives, with Alternative 3 having the lowest capital cost associated with slurry

wall construction and lowest O&M cost due to the greater cost reductions in O&M associated with reduction in GWTP operation and reduction in monitoring costs (this alternative does not require full extraction of groundwater). Alternatives 2, 4, and 6 have the highest O&M costs of all the alternatives because it is assumed that GWTP operations will continue for 30 years with no reduction in extraction rates.

Alternative	Capital Cost	O&M Cost	Total NPV
1	$0	$0	$0
2	$14.56	$19.60	$34.16
3	$6.41	$12.24	$18.65
4	$13.11	$19.39	$32.50
5	$19.52	$13.15	$32.67
6	$102.23	$19.39	$121.62

Costs given in millions
NPV – net present value

1 INTRODUCTION

AECOM Technical Services, Inc. (AECOM) has been contracted by the U.S. Army Corps of Engineers (USACE), Tulsa District, to perform remediation activities at various sites at the former Longhorn Army Ammunition Plant (LHAAP), Karnack, Texas. This work is being performed under USACE Huntsville district's Worldwide Environmental Remediation Services (WERS) Contract No. W912DY-09-D-0059 Task Order No. DS01.

This report presents a preliminary evaluation of the occurrence of natural attenuation (NA) of methylene chloride (MC), trichloroethene (TCE), and perchlorate present in the Shallow Zone and Wilcox Formation groundwater at LHAAP-18/24 (the site). This analysis is important if NA is to be considered as a remedial process applicable at the site.

The operation of the site groundwater extraction and treatment system distorts the natural groundwater flow patterns in the area and reduces chemicals of concern (CoC) concentrations by removing contaminated groundwater and causing clean or contaminated groundwater to flow in from the adjacent areas. For this reason, extraction wells, interception collection trenches (ICTs), and wells that are within the cone of depression of extraction wells and ICTs cannot be evaluated for NA. Any observed chemical attenuation at such locations is likely to be overshadowed by operation of the groundwater extraction system. Monitoring wells located outside the ICTs and extraction wells' direct radius of influence may be evaluated for evidence of NA. Monitoring wells in the Deep Zone may also be reasonably evaluated for evidence of NA because they are below the depth of the groundwater extraction wells and trenches and in the majority of the site areas are separated from the Shallow Zone by a Wilcox clay layer. Monitoring wells located outside the ICTs and extraction wells' direct radius of influence, but within the containment area, may also be evaluated for evidence of NA.

This evaluation of the NA processes at the site will serve as the basis to consider the application of Enhanced Attenuation (EA) processes at the site in the event NA combined with established site remedial approaches may not meet remediation goals within a reasonable timeframe.

1.1 LHAAP Background

LHAAP-18/24, also known as Burning Ground No. 3 and the Unlined Evaporation Pond (UEP), is located in the southeastern section of LHAAP and covers an area of approximately 34.5 acres. LHAAP-18/24 is located between Avenue Q to the southeast and Harrison Bayou to the northwest. LHAAP-17 (Burning Ground No. 2) is to the southwest. LHAAP-18/24 had been used since 1955 as a burial and burning ground for various industrial wastes and hazardous wastes generated at LHAAP. Burned wastes include solvents, oil, and red phosphorus. Buried wastes include rocket motor washout residues, illuminating mixtures, oxidizing agents, solvents, oils, and detergents. The former UEP was constructed in 1963 to collect water from the washout of rocket motor casings and the process waste sumps. The water contained solvents, explosive compounds, and metal residues. The UEP was no longer used after 1984, and was closed down under RCRA in 1986 with the removal of the sludge and the capping of the impoundment. As part of the LHAAP-18/24 Interim Remedial Action (IRA), approximately 32,000 cubic yards of soil was excavated and treated by low temperature thermal desorption. In addition to the contaminated soil removal, a groundwater extraction system and a groundwater treatment plant were installed in 1997 to control the migration of contaminated groundwater (Plexus, 2005).

Current operations at LHAAP-18/24 include the operation of the groundwater extraction and treatment system.

1.2 Site Geology and Hydrogeology

1.2.1 Surface Water Hydrology

Harrison Bayou flows within approximately 200 feet of the western corner of LHAAP-18/24. There are no surface water bodies or watercourses running through the Site. Surface drainage occurs in all directions, but flow is generally directed toward Harrison Bayou to the West and by both natural and manmade ditches and drainage swales to the north. Harrison Bayou drains into Caddo Lake, which is located approximately one mile northeast of LHAAP-18/24. The extreme western corner of the Site is located within the 100-year floodplain of Harrison Bayou.

1.2.2 Site Geology

LHAAP-18/24 site falls completely within the area mapped as undifferentiated Quaternary alluvium in the geologic maps compiled by Virgil Barnes (Texas Bureau of Economic Geology, 1992).

Site stratigraphy consists of a relatively thin (10 to approximately 45 feet (ft)) cover of unconsolidated Quaternary alluvium atop semi-consolidated sandstones (sands) and shales (clays and silts) of the Eocene Wilcox formation. The contact between the Quaternary and Eocene units represents a significant erosional unconformity in the local geologic record.

Structurally, the site is located on the northwest edge of the Sabine uplift, a roughly circular dome-like geologic structure. Due to this feature, the Wilcox formation locally dips gently toward the northwest and not to the southeast as it does in much of the Texas coastal plain.

The Quaternary alluvial deposits that cover the Site were generated by two main fluvial systems: the Big Cypress Bayou and the Harrison Bayou fluvial systems. Big Cypress Bayou alluvium comprises the majority of the Site Quaternary alluvium. Its thickness ranges from 20 to 50 ft (USACE, 1993) and thins toward the west, away from Caddo Lake and the modern alluvial valley. A smaller portion of the alluvium at the site owes its origins to the Harrison Bayou. The Harrison Bayou occupies a small valley on the immediate northwestern border of the site. It locally incises into the older portions of the undifferentiated Quaternary alluvium and upstream, it likely cuts into any exposed or thinly covered Wilcox units.

In general, alluvium deposited by fluvial systems such as the Big Cypress and Harrison Bayou is characterized by laterally heterogeneous deposits of clays, silts, and sands. The Quaternary fluvial systems are characterized by:

- isolated sandy zones of higher permeability (typically preserved relict channels, point bars, or levees) surrounded by silts and clays of the relict flood plain.
- fining upward grain size pattern (or sequences) of sediments ranging in size from gravel at the base to clays and silts at the top in the channel or point bar sediments.
- sand, silty sands, silts, and clays are generally orange, light brown/grey, yellow and light brown, respectively.

The underlying Wilcox Formation consists of semi-consolidated sands and clays deposited in a larger scale fluvial-deltaic setting. The Wilcox units are characterized as follows:

- sands are broadly lenticular in morphology and more massive and homogeneous than the overlying alluvium sands.
- sands tend to be grey, greenish grey fine sands, though they weather to a variety of colors including red, yellow and brown (Texas Bureau of Economic Geology, 1975).
- lignite (black carbonaceous seams) is common throughout.
- locally, the top of the Wilcox Formation was identified as dark grey or blue grey clay (USACE, 1993).

According to Xue (1997), the upper Wilcox sands were deposited in fluvio-deltaic settings under transgressive conditions. During deposition, rising local sea level altered delta position over time resulting in the back filling and infilling with sediment (a process called aggradation) of fluvial or distributary channels. An upward trend towards finer sediment grain size would occur.

1.2.3 Site Hydrogeology

The current understanding of site hydrogeology recognizes the existence of two hydrogeologic units: a shallow unit from surface to a depth of approximately 45 feet below ground surface (bgs) (Shallow Zone), and a deep unit below the Shallow Zone. The Shallow Zone is comprised of Quaternary alluvium deposits and the Deep Zone is comprised of Wilcox units. Generally, these two units are separated by a contiguous clay layer that is believed to be present across the entire site with the exception of the area to the west and northwest towards Harrison Bayou (i.e., within the floodplain of Harrison Bayou).

As interpreted from the shallow groundwater elevations collected in May 2013, the groundwater in the Shallow Zone flows outwardly, in a radial direction, from the site to the surroundings (**Figure 1-6**, main text**)**. The potentiometric surface map for the Wilcox Formation also indicates the direction of flow in the northern portion of the site is similar to the Shallow Zone (**Figure 1-7,** main text).

Groundwater in the Deep Zone near LHAAP is currently used as a drinking water source As of May 2015, six active water supply wells near the LHAAP were identified (**Figure 1-2,** main text). All of these public water supply wells are located greater than two miles from the LHAAP-18/24 site. Water removal from these wells is not expected to affect groundwater flow at the site because of the remote locations of these wells from LHAAP and their depth of completion. There are three water supply wells located within LHAAP, upgradient of LHAAP-18/24. These water wells supply water to buildings currently in use on the installation. None of these wells are close to LHAAP-18/24, and none of these wells are used for drinking water. Two additional wells that had previously supplied water to the installation have been plugged and abandoned. None of the water supply wells are associated with or are in imminent danger of impairment from the localized contaminated groundwater at LHAAP-18/24.

1.3 Site Conceptual Model

Industrial operations that heavily used chlorinated solvents, the systematic storage and handling of substantial volumes of the chlorinated solvents, the burial and burning of wastes, etc. at

LHAAP-18/24 from 1955 through 1984 was probably the source of the groundwater contamination. The soil is not a media of concern at LHAAP-18/24 since contaminants in the soil do not pose significant risk of human health effects, ecological effects, or groundwater contamination by leaching.

It is assumed most of the contaminant mass present in groundwater was likely released as high concentrated solutions. After their release, the contaminants travelled along preferential pathways through the vadose soils to the saturated zones. Since chlorinated solvents are denser than water, they sank vertically in the saturated zone with minimal influence by groundwater movement and little or no dilution. Accordingly, plumes of highly concentrated contaminants formed on top of confining layers. Significant contaminant mass moved into low permeability confining layers either by direct percolation or by diffusion from coarse-grained layers. Some mass was incorporated into groundwater by dilution and was transported outwardly, in a radial direction, from the release area to the surrounding areas. The potential existence of plumes of high concentration and the mass absorbed by the confining layers may serve as a long-term secondary source from which contaminants will be released to groundwater by diffusion.

The identified CoCs in the Shallow Zone groundwater at LHAAP-18/24 are: 1) nine organic compounds; 1,1,2-trichloroethane (1,1,2-TCA), , tetrachloroethene (PCE), TCE, cis-1,2-dichloroethene (DCE), vinyl chloride (VC), MC, bromodichloromethane, 1,3,5-trinitrobenzene, and benzene; 2) perchlorate, and 3) six metals (antimony, arsenic, barium, chromium, cobalt, and nickel), and 4) 1,4-dioxane. Based on historical documentation, risk assessment, and comparison of detected concentrations to cleanup levels, it is assumed that TCE, MC, and perchlorate are the most significant CoCs.

Groundwater analytical data collected in 2013 from existing and newly installed groundwater monitoring wells expanded the understanding of the presence and distribution within and outside the containment area of MC, TCE and perchlorate in the Shallow Zone and Wilcox water-bearing zones. The distribution of MC, TCE and perchlorate in the Shallow Zone and Wilcox water-bearing zones are presented in **Figures 1-9 to Figures 1-14** of the main text**.**

2 DESCRIPTION OF NATURAL ATTENUATION

Every natural system has a capacity to attenuate contaminants through a variety of physical, chemical, and biological processes. The effectiveness of the NA process is controlled by the physicochemical characteristics of the contaminants of concern, and the physical, chemical, biological and hydrogeological properties of the media. Consequently, characterization is needed to identify and estimate the contribution of the physical, chemical, and biological processes in the reduction of contaminants in the impacted media and properly evaluate the system's natural capacity to attenuate contaminants.

The NA processes, as recognized in the Office of Solid Waste and Emergency Response (OSWER) Monitored Natural Attenuation (MNA) Directive, are defined in the following quotation [USEPA, 1999]:

"*The "natural attenuation processes" that are at work in such a remediation approach* [MNA] *include a variety of physical, chemical, or biological processes that, under favorable conditions, act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in soil or groundwater. These in-situ processes include biodegradation; dispersion; dilution; sorption; volatilization; radioactive decay; and chemical or biological stabilization, transformation, or destruction of contaminants.*

Monitored natural attenuation is appropriate as a remedial approach only when it can be demonstrated capable of achieving a site's remedial objectives within a time frame that is reasonable compared to that offered by other methods and where it meets the applicable remedy selection program for a particular OSWER program. EPA, therefore, expects that monitored natural attenuation typically will be used in conjunction with active remediation measures (e.g., source control), or as a follow-up to active remediation measures that have already been implemented"

The OSWER MNA Directive outlines a three-tiered approach for the evaluation of MNA as a remedy. This approach includes the use of three lines of evidence:

- Historical groundwater and/or soil chemistry data that demonstrate a clear and meaningful trend of decreasing contaminant mass and/or concentration over time at appropriate monitoring or sampling points that are not solely the result of plume migration.
- Hydrogeologic and geochemical data that can be used to demonstrate indirectly the type(s) of natural attenuation processes active at the site, and the rate at which such processes will reduce contaminant concentrations to required levels (e.g., characterization data may be used to quantify the rates of contaminant sorption, dilution, or volatilization, or to demonstrate and quantify the rates of biological degradation processes occurring at the site.)
- Data from field or laboratory microcosm studies which directly demonstrate the occurrence of a particular natural attenuation process at the site and its ability to degrade the contaminants of concern.

Specific steps for evaluating NA of chlorinated solvents are provided in the USEPA technical protocol, generally referred to as the "EPA MNA Protocol" (USEPA, 1998).

According to the EPA MNA Protocol, NA in ground-water systems results from the integration of several subsurface attenuation mechanisms that are classified as either destructive or

nondestructive. Biodegradation is the most important destructive attenuation mechanism, although abiotic destruction of some compounds does occur. Nondestructive attenuation mechanisms include sorption, dispersion, dilution from recharge, and volatilization (USEPA, 1998).

The OSWER MNA Directive was used as the main guidance during this natural attenuation evaluation.

2.1 Methylene Chloride

MC, also called dichloromethane, is a volatile, colorless liquid with a chloroform-like odor. MC is used in various industrial processes such as: paint stripping, pharmaceutical manufacturing, paint remover manufacturing, metal cleaning and degreasing, adhesives manufacturing and use, polyurethane foam production, film base manufacturing, polycarbonate resin production, and solvent distribution and formulation.

Industrial operations, with the potential to contribute to MC contamination, took place across the site for a number of years. These operations included the washing out of rocket motors to remove materials heavily laden with perchlorate and the storage of substantial volumes of the solvent.

It is assumed MC was likely released as free product and travelled along preferential pathways through the vadose soil until it reached the saturated zone. MC is also a byproduct of carbon tetrachloride and chloroform dechlorination. Chloroform is detected in site groundwater, but at concentrations much smaller and more sporadically than MC concentrations. Therefore, MC presence at the site is not attributed to the degradation of chloroform.

The general breakdown mechanism for MC through the kinetic reactions indicated below (Tanabe, 1961):

MC: $CH_2Cl_2 + 2e^- + H^+ \Longrightarrow CH_3Cl + Cl^-$

Chloromethane: $CH_3Cl + 2e^- + H^+ \Longrightarrow CH_4 + Cl^-$

2.1.1 Sorption, Dispersion, Dilution, and Volatilization of Methylene Chloride

MC is not strongly sorbed to soils or sediments (Dilling et al. 1975). Since MC has a low soil organic carbon partitioning coefficient (K_{oc} = 25), it is very highly mobile in soils (Bahnick and Doucette 1988) and easily leaches from soils into groundwater.

MC dissolves in water slowly. The experimental half-life reported for the hydrolysis reaction, at neutral conditions, is approximately 18 months at 25 °C. However, the rate of reaction varies greatly with changes in temperature and pH. A hydrolytic half-life of 14 days was reported for methylene chloride in acidic solutions at 80–150 °C ((Dilling et al. 1975).

Due to its high vapor pressure, most of the MC released to the environment will partition to the atmosphere, where it degrades by reaction with photochemically produced hydroxyl radicals

with a lifetime of 6 months. Its high Henry's law constant (0.002 atm/m^3/mol) indicates that volatilization from moist soil is also likely.

Under acidic and basic conditions and in the temperature range of 80-150°C, the hydrolysis of MC results in the formation of formaldehyde and HCl (Fells and Moelwyn-Hughes, 1958). Under site conditions, the hydrolysis of MC in the saturated zone is expected to be slow.

2.1.2 Methylene Chloride Biodegradation

Degradation of MC was found to occur in soils with a wide range of concentrations under both aerobic and anaerobic conditions. The rate of biodegradation was found to be dependent on soil type, substrate concentration, and redox state of the soil and appears to be accelerated by the presence of elevated levels of organic carbon.

In groundwater, MC can serve as a growth substrate for an extensive number of aerobic and anaerobic bacteria. In addition, various co-metabolic transformations have been documented under oxic and anoxic conditions (Brunner et al. 1980; Tabak et al.1981).

The *Acinetobacter* sp. has been shown to use oxygen or nitrate ion as the electron acceptor. These bacteria are able to efficiently utilize MC as a carbon and energy source. MC has been observed to undergo degradation at a rapid rate under aerobic conditions. Justicia-Leon, et al. (2012) was able to use a Dehalobacter sp. from river sediment to degrade 20 milligrams per liter (mg/L) of MC in four weeks with MC as the sole substrate. The culture developed after repeated cycles of MC dosing and degradation was able to consume MC at a rate of 4 mg/L/day and tolerated a concentration of at least 200 mg/L without apparent inhibition.

No reductive dehalogenation of MC in water has been observed in the presence of sodium sulfide and haematin, a common ferric iron porphyrin (Klecka & Gonsior, 1984). Also, the biodegradation of MC in contaminated groundwater can be strongly inhibited in the presence of other contaminants such as 1,2-dichloroethane, xylene and ethylbenzene (Scholz-Muramatsu et al., 1988). Therefore, introduction of organic substrate to enhance anaerobic degradation of contaminants could result in reduction in MC degradation rates under anaerobic conditions due to competition associated with introduced organic substrates.

2.2 Trichloroethene

In pure state, TCE is a colorless or blue liquid with a sweet, chloroform-like odor. TCE is used primarily as a solvent to remove grease from metal parts in the metal and automotive industries. It is also an ingredient in adhesives, paint and varnish removers, typewriter correction fluids, rug-cleaning fluids, spot removers, sheet vinyl flooring, and pepper sprays.

Industrial operations, with the potential to contribute to TCE contamination, took place across the site for a number of years. These operations included the degreasing of tank bottoms, cleaning operations, and the storage of substantial volumes of the solvent.

It is assumed TCE was likely released as free product and travelled along preferential pathways through the vadose soils until it reached the saturated zone. TCE is also a byproduct of PCE dechlorination. However, generally, PCE is not present in the site soil and groundwater.

The effective destruction of TCE generally involves the stepwise degradation of compounds through reductive dechlorination. The most robust pathway for treatment of TCE is:

TCE ⟹ DCE ⟹ VC ⟹ ethene

The generalized TCE and daughter products breakdown mechanisms are presented below:

TCE: $C_2HCl_3 + H^+ + 2e^- \Longrightarrow C_2Cl_2H_2 + Cl^-$

DCE: $C_2Cl_2H_2 + H^+ + 2e^- \Longrightarrow C_2ClH_3 + Cl^-$

VC: $C_2ClH_3 + H^+ + 2e^- \Longrightarrow C_2H_4 + Cl^-$

With each sequential stage, the TCE concentration and daughter products in groundwater change. Where destruction of TCE is complete, the results should mimic the theoretical chain, often described as a "cascade", of intermediates progressing from TCE through ethene. If the TCE destruction is incomplete, then one or more of the compounds undergoing treatment would build up. In fact, a crucial step in the above sequence is the reaction that causes transformation of DCE to VC. This step is slow or insignificant conversion occurs and DCE accumulates. This has been referred to as "stalling".

2.2.1 Sorption, Dispersion, Dilution, and Volatilization of TCE

Since TCE is dense and has a moderate solubility, adsorption to soil and dispersion have negligible effect in the overall transport through the unsaturated zone.

TCE is highly volatile, therefore it volatilizes as it moves in the unsaturated zone. Due to its moderate solubility, TCE vapors will not dissolve in the soil moisture but will eventually move upward, out of the soil matrix into the atmosphere.

Since TCE is very dense, a concentrated solution will tend to sink vertically with minimal influence by groundwater movement and little or no dilution. Accordingly, pools of highly concentrated TCE may form on top of confining layers. Significant mass may move into low permeability confining layers by diffusion. TCE pools and mass absorbed by the confining layers may serve as a long-term source from which TCE is released to the groundwater by diffusion.

2.2.2 TCE Abiotic Reduction

Abiotic degradation mechanisms involve chemical reactions to reduce the chlorinated hydrocarbon without biological processes. These mechanisms include hydrolysis, elimination, and abiotic reductive dechlorination.

Hydrolysis is a substitution reaction in which the chlorinated hydrocarbon reacts with water to substitute a chlorine atom with a hydroxyl group, producing organic alcohols, or acids. Elimination reactions involve the removal of a hydrogen and a chlorine atom (sometimes referred to as dehydrohalogenation) from a chlorinated hydrocarbon to form the corresponding daughter product (Vogel and McCarty 1985). Hydrolysis is more effective in less chlorinated

hydrocarbons (DCE and VC) while elimination reactions are more effective in more chlorinated hydrocarbons (PCE and TCE).

Abiotic reductive dechlorination is a process through which chlorinated ethenes such as PCE, TCE, DCE, and VC can break down in contact with some specific minerals. Abiotic reductive dechlorination of TCE can occur in the presence of natural Fe(II)- and S(II)-containing minerals, such as Pyrrhotite (FeS), greigite (Fe_3S_4), pyrite (FeS_2), magnetite (Fe_3O_4), and various green rusts such as Fougèrite $\{[Fe^{2+}{}_4Fe^{3+}{}_2(OH)_{12}][CO_3].3H_2O\}$ (Kriegman-King and Reinhard, 1994; Sivavec et al. 1995, and Sivavec and Horney 1997). In 2002, *cis*-1,2-DCE (*cis-1,2-DCE*) was shown to be abiotically degraded by magnetite at rates comparable to biological processes (Ferrey and Wilson, 2002).

At sites with naturally occurring reduced iron or at sites with iron-rich mineralogy and strong reducing conditions, ferrous iron minerals can degrade TCE without the corresponding production of common biological daughter products such as *cis-1,2-DCE* and VC. Some studies have shown that acetylene is the most common byproduct of abiotic degradation of PCE, TCE and DCE.

2.2.3 TCE Biodegradation

McCarty and Semprini, (1994) studies have revealed that three types of metabolic processes are generally involved in the biological degradation of TCE: 1) reductive dechlorination: an anaerobic process in which chlorinated ethenes are used as electron acceptors; 2) co-metabolism: chlorinated ethenes are anaerobically degraded as a result of biochemical interactions, which yield no benefit to bacteria; and 3) direct oxidation: an aerobic or anaerobic process in which sparsely chlorinated ethenes are used as electron donors.

Reductive Dechlorination

During reductive dechlorination, TCE undergoes complete sequential reductive dechlorination under anaerobic conditions, yielding ethene or ethane as final products (Maymo-Gatell et al., 1999).

The intermediate daughter products of reductive dechlorination are cis-1,2-DCE, *trans*-DCE, 1,1-DCE and VC. According to Bouwer (1994), cis-1,2-DCE is a more prevalent intermediate than *trans*-DCE, and 1,1-DCE is the least prevalent intermediate during reductive dechlorination.

For reductive dechlorination to occur, the presence of sufficient concentrations of electron donors for energy metabolism is necessary. The presence of other electron acceptors such as oxygen, nitrate/insoluble manganese, insoluble ferric iron, sulfate and carbon dioxide, respectively, in the order of bacterial preference, can negatively impact TCE dechlorination (Byl and Williams, 2000).

The microorganisms that participate in TCE reductive dechlorination differ significantly in their ability and potential to dechlorinate TCE. It has been found that not all TCE dechlorinating organisms can degrade TCE completely. *Dehalococcoides ethenogenes* strain 195 (Maymo-Gatell et al., 1997) and *D. ethenogenes* (Hendrickson et al., 2002) were reported to reduce TCE to ethene. However, other bacteria only partially dechlrorinate TCE producing intermediate product, such as cis-1,2-DCE and VC (e.g., *Dehalospirillium multivorans* (Neumann et al.,

1994), *Enterobacter agglomerans* (Sharma and McCarty, 1996) and *Desulfitobacterium* sp. strain PCE1 (Gerritse et al., 1996)).

Co-metabolism

It has been reported the degradation of TCE occurs by aerobic co-metabolism. According to Alvarez-Cohen and McCarty (1991), methane monooxygenase (MMO) produced by methanotrophs bacteria converts TCE into a TCE epoxide, which breaks down into carbon monoxide, formate, glyoxylate, and chlorinated acids in aqueous environment. These compounds are subsequently metabolized by methanotrophs and heterotrophs either collectively or individually, forming the final products (i.e., carbon dioxide and cell mass). Besides methane-oxidizing bacteria, other bacteria, such as toluene oxidizers and phenol oxidizers, can also produce oxygenases in response to phenol or toluene, which initiate the oxidative degradation and mineralization of TCE (Fan and Scow, 1993).

Not only TCE, but also its intermediates (DCE and VC) produced from reductive dechlorination can be co-metabolized.

Competition for the oxygenases among natural substrates (for example, CH_4, NH_3 or toluene) and chlorinated solvents has been documented by Semprini et al. (1991). Other environmental factors, such as temperature and soil moisture, also influence the co-metabolism activities.

Toluene-oxidizing bacteria (e.g., *Pseudomonas putida* F1) can produce a dioxygenase during toluene oxidation that co-metabolizes TCE (Wackett and Gibson, 1988). Winter et al. (1989) reported the complete TCE degradation by a toluene para-monooxygenase produced by *Pseudomonas mendocina* KR1 when vapor-phase toluene was supplied as a sole carbon source. *Pseudomonas cepacia* G4, *Pseudomonas cepacia* G4PR1, *Pseudmonas mendocina* KR1, *Pseudomonas putida* F1, and *Methylosinus trichosporium* OB3b have been proven to degrade TCE by co-metabolic processes (Sun and Wood, 1996).

Direct Oxidation

During the direct oxidation process, microorganisms obtain energy and organic carbon from the chlorinated ethenes that undergo oxidative biodegradation (i.e., DCE and VC). In a study with VC conducted in iron-reducing aquifer sediments, Bradley and Chapelle (1996) noted a complete mineralization of VC in the presence of Fe(III), which was attributed to the direct oxidation of chlorinated ethenes.

Closely related strains of Acinetobacter species, of Bacillus species (mainly Bacillus subtilis and Bacillus cereus), and strains of Achromobacter xylosoxidans, Klebsiella and Pseudomonas aeruginosa, have been reported to be able to degrade cis- and trans-DCE directly by using them as their energy source (Olaniran et al., 2008).

2.3 Perchlorate

Perchlorate (ClO_4^-) is a soluble anion typically found in the form of perchlorate acid and salts such as ammonium perchlorate, sodium perchlorate and potassium perchlorate. Among these chemicals, ammonium perchlorate (NH_4ClO_4) is the most prevalent form of this compound. Ammonium perchlorate is used as an energetic booster or oxidant in solid propellant for rockets and missiles, and was likely leached into site groundwater via leaks and spills during rocket motor washout activities at LHAAP-18/24.

Ammonium perchlorate is extremely soluble (200 g/L at 25°C) and very mobile in aqueous systems, and can persist in the environment for many decades under aerobic conditions because of its resistance to reaction with other available constituents.

However, perchlorate can be reduced to chlorate (ClO_3^-), which can be further reduced to chlorite (ClO_2^-), then to the innocuous final product as chloride (Cl^-) and oxygen (Rikken et al., 1996), as indicated in the following pathway:

$$ClO_4^- \Longrightarrow ClO_3^- \Longrightarrow ClO_2^- \Longrightarrow Cl^- + O_2$$

Perchlorate reduction occurs depending on the reductant through the kinetic reactions indicated below (Urbansky, 1998):

$$ClO_4^- + 8H^+ + 8e^- \Longleftrightarrow Cl^- + 4H_2O \qquad E^0 = 1.287V$$

$$ClO_4^- + 2H^+ + 2e^- \Longleftrightarrow ClO_3^- + H_2O \qquad E^0 = 1.201V$$

$$2H_2O \Longleftrightarrow 4H^+ + 2O^{-2} \qquad E^0 = -1.229V$$

2.3.1 Sorption, Dispersion, Dilution, and Volatilization of Perchlorate

Sorption into soils is not expected to attenuate perchlorate concentrations because it absorbs weakly to most soil minerals. Both, clay particles in the soil and perchlorate, are negatively charged and consequently they do not bond. However, sorption of perchlorate appears to occur in soils with appreciable anion-exchange capacities (AEC) (acidic soils). These soils act like anion exchangers, and perchlorate is sorbed by the replacement of other anions such as chloride, sulfate and nitrate.

Natural chemical reduction in soil is also not expected to be significant. Perchlorate is highly soluble; therefore, the movement of perchlorate in soil is largely a function of the amount of water present. If sufficient infiltration occurs, perchlorate will completely leach from the unsaturated zone and reach groundwater. No partitioning coefficients or degradation rates in the environment are reported in the literature for perchlorate.

Dilution and dispersion are considered to be the most important processes influencing the fate and transport of perchlorate once it reaches groundwater. In dilute concentrations, perchlorate behaves conservatively, with the center of mass of the plume moving at the same average velocity as the water. Dispersion will result in the contaminant front actually moving faster than the average groundwater velocity.

Since perchlorate ions are very dense, a concentrated solution will tend to sink vertically with minimal influence by groundwater movement and little or no dilution. Accordingly, brine pools may form on top of confining layers and significant perchlorate mass may move into low permeability confining layers by diffusion. The brine pools and perchlorate mass absorbed by the confining layers may serve as a long-term source of dissolved contaminant as perchlorate is

released to the groundwater by diffusion. Data from Post-Screening Investigation (PSI) and PSI Addendum conducted in 2013 and 2014 confirm this observation.

2.3.2 Percolate Reduction by Metal Cation

As referenced by Urbansky, 1998, titanium(III), vanadium(II), and chromium(II) have been shown to reduce perchlorate to chloride in acidic aqueous solution at ambient temperature. King and Garner (King and Garner, 1954) published the results of the first kinetic investigation of the reaction of vanadium(II) and vanadium(III) with perchlorate, as shown in the following reactions:

$$8V^{2+} + ClO_4^- + 8H^+ \Longrightarrow 8V^{3+} + Cl^- + 4H_2O$$

$$8V^{3+} + ClO_4^- + 4H_2O \Longrightarrow 8VO^{2+} + Cl^- + 8H^+$$

Of the tested percolate reducing metal cations, chromium is a recognized pollutant; consequently its use as percolate reducing agent is precluded.

2.3.3 Perchlorate Biodegradation

Perchlorate can be reduced to chlorite in the presence of indigenous perchlorate-reducing microbes under anaerobic conditions (Ground-Water Remediation Technologies Analysis Center [GWRTAC], 2001).

Perchlorate-degrading microorganisms have been found to be widespread in the subsurface environment at concentrations ranging from one to thousands of bacteria per gram of water, wastewater, sediment, and soil (Logan et al., 2001; Coates et al., 1999; and O'Connor et al., 2002). Approximately 70 percolate reducing bacteria have been tested in both pure and mixed cultures (Bruce et al., 1999; Coates et al., 1999; Wolterink et al., 2003). Logan (2001) tested seven bioreactor systems with different microorganism cultures and substrates. Logan concluded that a Wollinella succinogenes HAP-1 mixed culture in a protein substrate (aged brewer's yeast, cottonseed protein, or whey powder) effectively reduced a solution containing 7,750 ppm of perchlorate.

Effect of nitrate on perchlorate biodegradation

Previous research demonstrated that most perchlorate respiring bacteria such as *D. suillum* can utilize nitrate as a suitable electron acceptor. According to the observation of Chaudhuri, 2002 and Tipton, 2003, when a culture of *D. suillum* is inoculated into fresh medium containing equimolar amounts of both nitrate and perchlorate, no perchlorate reduction was observed until nitrate was completely consumed. These investigations concluded that nitrate is a competing ion in perchlorate reduction but co-reduction of both perchlorate and nitrate is possible.

Effect of oxygen on perchlorate biodegradation

According to the observation of Chaudhuri, 2002, when *D. suillum* was grown anaerobically with perchlorate as the only electron acceptor, perchlorate removal was rapid. However, if air was introduced, perchlorate reduction was immediately inhibited. This finding agreed with previous studies (Coates et al., 1999) that concluded perchlorate reduction is inhibited in aerobic conditions, even at low dissolved oxygen (DO) levels.

Effect of other electron donors on perchlorate biodegradation

Sulfur and Thiosulfate:

Bardiya and Bae, 2005, tested for perchlorate reduction with thiosulfate as an e- donor. Bardiya and Bae, 2005 assumed that since sulfur utilizing bacteria are capable of denitrification, and many perchlorate reducers are denitrifiers, then sulfur reducing bacteria may be capable of reducing perchlorate. In the Bardiya and Bae, 2005 experiment, the bacteria failed to grow and reduce perchlorate with thiosulfate as an e-donor, thus concluding that reduced sulfur compounds such as sulfur and thiosulfate could not serve as e- donors for perchlorate reduction.

Acetate:

Bardiya and Bae, 2005, also observed during the experimentation that in the presence of acetate, the reduction of perchlorate was stimulated. Also, the reduction of both perchlorate and nitrate was observed.

3 ATTENUATION EVALUATION RESULTS

This section presents the results of the attenuation evaluation performed at wells MW-1, MW-2, MW-4, MW-5, MW-7, MW-8, MW-14, MW-21, MW-23, AWD-1, 109, 120, and 18WW08. These wells represent the area inside the containment where influence of groundwater extraction is prominent and areas outside the containment where groundwater extraction influence is absent (MW-8 and 18WW08). The historical groundwater concentration data collected for these wells were examined for evidence of attenuation (for wells inside the containment) and NA (for wells outside the containment) such as declining contaminant concentrations and/or the presence of degradation products. For the purposes of this evaluation, only concentrations detected above the laboratory Sample Quantification Limit (SQL) are plotted in the graphs. Concentrations below the SQL are represented as gaps in the graphs and were not used in the estimation of the attenuation rates.

3.1 Limited Natural Attenuation Evaluation

In May 2013, AECOM collected NA data from three perimeter wells (MW8 in the southwest, 18WW08 in the northwest, and 18CPTMW18 in the northeast) to evaluate the site potential for NA. The collected NA data included dehalococcoides count, TCE and VC degradation genes, compound-specific isotope analysis (CSIA) for TCE and cis-DCE, degradation gases (ethane, ethene, and methane), ferrous iron, alkalinity, chloride, and sulfate. The results of the NA sampling are summarized in **Table A-1**.

The results of the 2013 sampling showed no microbial population or expressive genes were present in the collected samples. CSIA results for TCE did not show enrichment that would be associated with biodegradation, degradation gases were not present, and ferrous concentrations also indicate little reduction is occurring. Monitoring well 18CPTMW18 had positive oxidation reduction potential (ORP) (157 millivolt - mV) and no reduction in alkalinity, indicating absence of anaerobic biodegradation. 18WW08 had a positive ORP (164 mV) but reduced alkalinity with little concentration of ferrous iron, indicating slight anaerobic activity is occurring. Similarly, MW8 had a positive ORP at 298 mV and no discernible bioactivity, although alkalinity in the well appears to have been consumed along with sulfate which is present at much reduced levels compared to the other wells. MW8 had the highest contaminant concentration among the three wells. However, the pH in this well is 5.04 standard units, which makes conditions difficult for biological activity. Based on the obtained results, AECOM concludes that biodegradation was not occurring at any appreciable level in these selected wells.

Nevertheless, a preliminary review of the historical data showed clear indications of NA occurring throughout the MC, TCE, and perchlorate groundwater plumes. An evaluation of the NA evidence is presented below.

Table A-1: Monitored Natural Attenuation Parameters - LHAAP-18/24

Sample ID: Sample Date:	Units	18CPTMW18-051513 5/15/2013	18WW08-051513 5/15/2013	MW8-043013-FD 4/30/2013	MW8-051613 5/16/2013

ND - non detect

U - below detection limit

ug/L - microgram per liter

3.2 Attenuation Evaluation Process

The first-order decay rates of contaminants and the time it takes to achieve contaminant cleanup levels for selected wells were estimated using an Excel® based calculator developed by the Utah Leaking Underground Storage Tank program. The calculator is based on EPA's Ground Water Issue paper EPA/540/S-02/500, "Calculation and Use of First-Order Rate Constants for Monitored Natural Attenuation Studies," by Newell, Rifai, Wilson, Connor, Aziz and Suarez, November 2002.

The formula for calculating a first-order decay rate is:

$$\mathbf{t = - [\ln(CCL/Co)] / k_{point}}$$

t = time to achieve cleanup level, years

CCL = Cleanup level for contaminant of concern, mg/L

Co = Initial concentration of contaminant of concern, mg/L

k_{point} = First-order decay rate of contaminant of concern, $year^{-1}$

Values reported below the SQL were not used in the calculations. The historical concentrations of key wells inside and outside the containment were used in the construction of concentration trend graphs to assist in the interpretation of the data. The following presents the trend analysis for TCE, MC, and perchlorate for wells located inside (influenced directly by groundwater extraction) and outside (not influenced directly by groundwater extraction) the containment area.

The trend analysis for wells highly influenced by groundwater extraction provides information associated with contaminant removal rate associated with the extraction system and NA. However, it is believed that the dominant influence of concentration decrease, where it is observed, is associated with groundwater extraction. The rate of NA is likely orders of magnitude smaller than rate of mass extraction via the groundwater extraction system. For these wells, NA effects cannot be isolated from groundwater extraction influence. Changes in concentrations for wells outside the influence of groundwater extraction are associated with NA only. Similarly, former injections in ICT6 and ICT9 that had caused dilution of contaminant concentrations or that had pushed contaminants away from the injection zone influence NA calculations. In these locations under the influence of injection water, the majority of observed concentration changes is likely caused by injection rather than NA conditions. Generally, the influence of injection in ICT9 is observed in MW-22 and the influence of injection in ICT6 might have influenced concentrations in MW-1.

3.2.1 Perchlorate

The highest concentration of perchlorate was identified in June 2014 in plugged well outside the containment (18CPTMW22) at a concentration of 106,000 μg/L. In June 2016, the highest perchlorate concentrations in the Shallow Zone occur in monitoring wells 120 (32,700 ug/L), MW-23 (65,200 ug/L), MW-5 (31,300 μg/L), 18WW17 (82,900 μg/L), and MW-21 (26,100 ug/L). Concentrations decrease away from these locations (**Figure 1-9, main text)**. The following presents the trend analysis for perchlorate in wells inside and outside the containment area.

The evaluation of perchlorate degradation evidence via analysis of daughter products is complicated by the fact that the daughter products of perchlorate degradation are degraded faster than perchlorate and do not accumulate in groundwater.

3.2.1.1 MW-2 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show a decreasing trend in perchlorate concentrations in well MW-2 (see **Figure A-1**). Analysis of the concentration data from October 2000 to June 2016 shows an attenuation rate of 0.3312 per year (k_{point}) with a correlation coefficient (R^2) of 43%. At the most recently detected concentration (June 2016) of 33.3 μg/L and current degradation rate, the time to achieve the cleanup level for perchlorate of 17 μg/L (the Texas Risk Reduction Program [TRRP] Tier 1 Groundwater Residential Protective Concentration Level [PCL] hereafter referred to as the PCL) in well MW-2 is estimated to be approximately 2.1 years.

3.2.1.2 MW-1 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show a decreasing trend in perchlorate concentrations (**Figure A-2**). Analysis of the concentration data from October 2000 to June 2016 shows an attenuation rate of 0.0775 per year. At the most recent concentration in June 2016 of 14,800 μg/L and this degradation rate, the time to achieve the PCL in well MW-1 is estimated to be approximately 87 years.

3.2.1.3 MW-4 (Influenced by Groundwater Extraction)

Results from October 2000 to September 2012 show a slow decreasing trend in perchlorate concentrations (**Figure A-3**). Well MW-4 is located north of well MW-2 and south of ICT-14A. Analysis of the concentration data from October 2000 to September 2012 shows an attenuation rate of 0.0701 per year with a correlation coefficient of 20%. At the September 2012 concentration of 12,000 μg/L and this degradation rate, the time to achieve the PCL in well MW-4 is estimated to be approximately 94 years.

3.2.1.4 MW-5 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show an increasing trend in perchlorate concentrations (**Figure A-4**). Migration of perchlorate to MW-5 continues to occur. MW-5 is closest to ICT-7 and ICT-13F. **Table 2-12** of the main report indicates during the 1st quarter 2016 the removal rate of perchlorate from ICT-7 is 557 mg/day or 0.448 lbs per year and from ICT-13F, the perchlorate removal rate is 1.09 mg/day or 8.8 E-04 lbs per year. It appears that ICT-7 and ICT-13F are not extracting high groundwater perchlorate concentrations near MW-5. The perchlorate concentration in ICT-7 is 339 ug/L in February 2016 and the concentration in ICT-13F is 1.14 ug/L in February 2016. These are small concentrations, indicating that neither ICT is pulling groundwater from the vicinity of MW-5 or the majority of the groundwater is being extracted from low concentration areas.

3.2.1.5 MW-21 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show an increasing trend in perchlorate concentrations in well MW-21 (**Figure A-5)**. Migration of perchlorate to MW-21 continues to occur. MW-21 is closest to ICT-14D. **Table 2-12** of the main report indicates the perchlorate removal rate during

the 1st quarter 2016 from ICT-14D is 17.1 lbs per year. Although ICT-14D is extracting significant amounts of perchlorate per year, the mass of perchlorate in this area is high enough such that the influence of this extraction rate is not immediately pronounced.

3.2.1.6 109 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show an overall decreasing trend in perchlorate concentrations (**Figure A-6**). Analysis of the concentration data from October 2000 to June 2016 shows an attenuation rate of 0.0817 per year with a correlation coefficient of 20%. At the June 2016 concentration of 1,820 μg/L and this degradation rate, the time to achieve the PCL in well 109 is estimated to be approximately 57 years. This is a long time for this location considering that this well is located adjacent to ICT-14B and ICT-14C with perchlorate removal rates as determined during the 1st quarter 2016 of 4.4 and 56 lbs per year, respectively. These data imply that there is a very high mass of perchlorate in this area that is likely present in fine-grained soils at very high concentrations (concentrations measured in ICT-14B and ICT-14C were 5,800 ug/L and 9,850 ug/L, respectively in February 2016), with release occurring over time.

3.2.1.7 AWD-1 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show a decreasing trend in perchlorate concentrations (**Figure A-7**). Analysis of the concentration data from October 2000 to June 2016 shows an attenuation rate of 0.5169 per year with a correlation coefficient of 66%. The most recent concentration in this well is below the PCL. This well is located adjacent to ICT-12E with a 1st quarter 2016 perchlorate removal rate of 140 lbs per year. These data indicate that there is a very high rate of mass removal of perchlorate from ICT-12E and the reduction in perchlorate is reflected in AWD-1 concentration.

3.2.1.8 MW-7 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show a slow decreasing trend in perchlorate concentrations (**Figure A-8**). Analysis of the concentration data from October 2000 to June 2016 shows an attenuation rate of 0.0958 per year with a correlation coefficient of 65%. At this degradation rate and a June 2016 concentration of 22,200 ug/L, the time to achieve the PCL level in well MW-7 is estimated to be approximately 75 years. This well is located adjacent to ICT-12A and ICT-12B with perchlorate removal rates of 4.8 and 142 lbs per year, respectively. These data indicate that there is a very high rate of mass removal of perchlorate from ICT-12B and the reduction in perchlorate concentration in groundwater is reflected in MW-7 concentration.

3.2.1.9 MW-14 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show a decreasing trend in perchlorate concentration until year 6 but an increase is observed in the past 4 years with no data available between years 6 and 12 (**Figure A-9**). Because the overall trend is increasing, a half-life or attenuation rate constant could not be determined. MW-14 is in the Wilcox Formation with an absence of a fine-grained layer separating the Wilcox Formation from the Shallow Zone. The increase in perchlorate concentration was measured in September 2012 while the GWTP was not operating since May 2012. The GWTP was also not operating during the summer of 2009. These two

episodes likely caused the vertical gradient to be downward with ensuing migration of CoCs from the shallow zone to the Wilcox Formation.

3.2.1.10 120 (Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 show a slight decreasing trend in perchlorate concentration until year 6, followed by a slight decrease in the past 3 years with no data between years 6 and 12 (**Figure A-10**). The overall trend is decreasing with an attenuation rate constant of 0.0421 per year with a correlation coefficient of 13%. At this degradation rate and a June 2016 concentration of 32,700 ug/L, the time to achieve the PCL in well 120 is estimated to be approximately 180 years. This well is located adjacent to ICT-12E and ICT-13A with 1st quarter 2016 perchlorate removal rates of 141 and 104 lbs per year, respectively. These data indicate that there is a very high rate of mass removal of perchlorate from these ICTs and the reduction in perchlorate concentration in groundwater is reflected in concentration in monitoring well 120. Monitoring well 120 is co-located with Wilcox well MW-14 and the high concentration exhibited in 120 is reflected in MW-14 in the absence of a clay layer.

3.2.1.11 MW-23 (Influenced by Groundwater Extraction)

Results from November 2001 to June 2016 show a steady increasing trend in perchlorate concentration (**Figure A-11**). Because the trend is increasing, a half-life or attenuation rate constant could not be determined. This well is located adjacent to ICT-10 which has not been operational since September 2007. Because no extraction occurred for the past 6 years adjacent to this well, the increasing trend implies that perchlorate is mobile or is leaching from fine-grained soils, and natural attenuation mechanisms, if occurring, are insignificant.

3.2.1.12 18WW08 (Not Influenced by Groundwater Extraction)

Results from May 2002 to June 2016 show a decreasing trend in perchlorate concentration (**Figure A-12**). Analysis of the concentration data shows an attenuation rate of 0.6239 per year with a correlation coefficient of 60%. The most recent concentration of perchlorate in this well was reported below detection (0.2 μg/L used in **Figure A-12**), which is below the PCL of 17 ug/L. This well is located in the northwest outside the direct influence of groundwater extraction but under the influence of Harrison Bayou. The decrease in perchlorate concentration in this well is certainly due to natural attenuation mechanisms of which dilution and biodegradation are the main mechanisms because perchlorate has high solubility and is not retarded by soil and it does not volatile. Therefore natural attenuation in the northeast of the site appears to be occurring.

3.2.1.13 MW-8 (Not Influenced by Groundwater Extraction)

Results from October 2000 to June 2016 showed an increasing trend in perchlorate concentration until May 2013, but was ensued with a decreasing concentration (**Figure A-13**) with an overall upward trend. A half-life or attenuation rate constant could not be determined for this well. This well is located in the southwest outside the direct influence of groundwater extraction. The increase in perchlorate concentration in this well is certainly due to perchlorate migration to the well and clearly indicates that natural attenuation mechanisms, even if occurring, are not important in this area of the site.

3.2.1.14 Summary of Perchlorate Concentration vs. Time Analysis

The evaluation of changes in perchlorate concentrations with time has shown slight evidence of the occurrence of attenuation. Of the analyzed wells, MW-1, MW-2, MW-4, MW-7, 109, AWD-1, 120, and 18WW08 show a decreasing trend in perchlorate concentration. Wells MW-5, MW-21, MW-14, MW-23, and MW-8 show increasing perchlorate concentrations.

The influence of the extraction of groundwater is pronounced in some areas such as in 109, AWD-1, and MW-2 and recently on 120. However, the influence of extraction is not observed in other areas such as MW-5 and MW-21. NA appears to be occurring to the northwest toward Harrison Bayou, but not in the southwest where high concentrations of perchlorate exist.

3.2.2 Trichloroethene

The distribution of TCE in the Shallow Zone is well defined in all directions with the highest concentrations identified in June 2016 in an approximately east-west axis between wells MW-2 (15,500 ug/L) and MW-21 (6,080 ug/L). High TCE concentrations were detected also in well 120 and AWD-1 (17,100 μg/L and 7,120 μg/L, respectively) in the western part of the site. Concentrations decrease away from these locations almost radially following groundwater flow directions (**Figure 1-11, main text)**. Well MW-2 is located near extraction well EW-1 and ICT-8 in the middle of LHAAP-18/24, well MW-21 is located near ICT-14D along the eastern edge of the site, and wells 120/AWD-1 are located near ICT-12E along the western edge of LHAAP-18/24. The following presents the trend analysis for TCE in wells inside and outside the containment area.

3.2.2.1 MW-2 (Influenced by Groundwater Extraction)

Results from May 2003 to June 2016 show a decreasing trend in TCE concentrations in well MW-2 (see **Figure A-14**). Analysis of the concentration data from May 2003 to June 2016 shows a decreasing trend with an attenuation rate of 0.1532 per year with a correlation coefficient of only 42%. At the most recent concentration of 15,500 μg/L in June 2016 and current degradation rate, the time to achieve the cleanup level (Maximum Contaminant Level [MCL] of 5 μg/L) in well MW-2 is estimated to be approximately 53 years.

Although MW-2 is located in close proximity to extraction well EW-1 (approximately 60 ft away) which may influence the TCE concentration trend, the concentration data of daughter products present a strong evidence of TCE degradation. As concentrations of TCE decrease in well MW-2, concentrations of cis-1,2-DCE, a byproduct of TCE degradation, have been increasing. **Figure A-15** indicates that cis-1,2-DCE has been observed with an increasing trend since 2007.

VC, a byproduct of cis-1,2-DCE degradation, has been detected above the SQL in MW-2 but in small concentrations. The low concentrations of VC in MW-2 (barely observed on **Figure A-15**) may be interpreted as the result of oxidizing conditions (high ORP and high DO) that support the degradation of VC and partial accumulation of cis-1,2-DCE, a term meaning cis-1,2-DCE stall (i.e., dechlorination stops at cis-1,2-DCE due to lack of appropriate bacteria in the formation). The low concentration of VC could also be associated with extremely high laboratory SQLs that make difficult the detection of VC at low concentrations.

3.2.2.2 MW-1 (Influenced by Groundwater Extraction)

Well MW-1 is located in the center of the site, between ICT-6 and ICT-8. Results from December 1996 to June 2016 show a decreasing trend in TCE concentrations (see **Figure A-16**). The analysis of the concentration data from December 1996 to June 2016 shows an attenuation rate of 0.1204 per year with a correlation coefficient of 60%. At the June 2016 concentration of 3,620 μg/L and the estimated degradation rate, the time to achieve the MCL in well MW-1 is estimated to be approximately 55 years. This is lower than the predicted duration for perchlorate at 87 year in MW-1.

As TCE concentrations decrease in well MW-1, the detection of cis-1,2-DCE and VC has been observed as far back as 1998 (**Figure A-17**). Low ORP and DO values have been measured in the field during several sampling events in well MW-1, indicating reducing conditions that are supportive of TCE and cis-1,2-DCE reductive dechlorination. These conditions may account for the decreasing trend in TCE concentrations and the appearance of cis-1,2-DCE and VC.

3.2.2.3 MW-4 (Influenced by Groundwater Extraction)

Similar to MW-1, well MW-4 shows evidence of TCE attenuation. Well MW-4 is located north of well MW-2 and south of ICT-14A in the peripheral of the TCE plume. Results from December 1996 to September 2012 show an increasing trend in TCE concentrations up to April 2000 and a decreasing trend since then (**Figure A-18**). The analysis of the concentration data from December 1996 to September 2012 shows an overall decreasing trend with an attenuation rate of 0.124 with a correlation coefficient of 45%. At the current degradation rate and concentration in September 2012 of 173 μg/L, the time to achieve the MCL in well MW-4 is estimated to be approximately 29 years.

As TCE concentrations decrease in well MW-4, the detection of cis-1,2-DCE has been sporadic while VC has been detected above the SQL more consistently (**Figure A-19**). The cis-1,2-DCE and VC concentrations seem to mimic the changes in TCE concentrations since 2009. The behavior of cis-1,2-DCE and VC does not follow the typical pattern for biotic degradation of TCE (i.e., decrease in TCE is accompanied by an increase in cis-1,2-DCE initially with subsequent decline as VC is formed) but it is more consistent with mass influxes of CoCs going through the well area under the influence of ICT-14A.

3.2.2.4 MW-5 (Influenced by Groundwater Extraction)

Results from January 1999 to June 2016 show a decreasing trend in TCE concentration (**Figure A-20**). MW-5 is closest to ICT-7 and ICT-13F. The analysis of the concentration data from January 1999 to June 2016 shows a decreasing trend with an attenuation rate of 0.0105 per year with a correlation coefficient of only 1.4%. At the current degradation rate and June 2016 concentration of 54 μg/L, the time to achieve the MCL in well MW-4 is estimated to be approximately 227 years.

As TCE concentrations decrease in well MW-5, the detection of cis-1,2-DCE and VC has been observed (**Figure A-21**) since 2007 at a concentration of greater than 10% of TCE concentration.

3.2.2.5 MW-21 (Influenced by Groundwater Extraction)

Results from September 1999 to June 2016 show a slow decreasing trend in TCE concentrations through September 2008 and a strong increasing trend from September 2008 to June 2016 in well MW-21 (**Figure A-22)**. The overall trend appears upward. It is possible that this trend is linked to the injection practice which occurred in September 2007 in ICT-9, which could have pushed CoCs outwardly towards MW-21 among other areas.

The presence of TCE degradation byproducts, namely cis-1,2-DCE and VC, is a clear indication that TCE degradation is occurring in the vicinity of well MW-21 (**Figure A-23**) or it is a result of withdrawing the TCE degradation products towards this area of the site due to the presence of ICT-14D. Nevertheless, the observed concentration trend does not follow a typical TCE reductive dechlorination pattern in which TCE is degraded and the daughter products are accumulated. The increasing trend in TCE and daughter products in well-21 is more likely to be attributable to the influence of groundwater extraction in ICT-14D than to NA. Under this scenario, mass influxes of TCE and daughter products are drawn toward MW-21 from surrounding vicinity by the groundwater extraction system.

3.2.2.6 109 (Influenced by Groundwater Extraction)

Results from January 1999 to June 2016 show an overall increasing trend in TCE concentrations (**Figure A-24**). This trend is the opposite of that observed for perchlorate, although the perchlorate concentrations are at least two orders of magnitude higher than TCE concentrations. This well is located adjacent to ICT-14B and ICT-14C with 1st quarter 2016 TCE removal rates of 0.14 and 63 lbs per year, respectively. These data imply that there is a very high mass of TCE migrating towards ICT-14C (concentration measured in ICT-14C was 11,100 ug/L in February 2016). The presence of cis-1,2-DCE indicates the occurrence of biodegradation (**Figure A-25)**, albeit, the source of cis-1,2-DCE may not be local to 109 due to effect of groundwater extraction adjacent to this well.

3.2.2.7 AWD-1 (Influenced by Groundwater Extraction)

AWD-1 is located near ICT-12E in the western boundary of LHAAP-18/24. Results from November 1994 to June 2016 show a decreasing trend in the TCE concentrations in this well (**Figure A-26)**. The analysis of the concentration data from November 1994 shows an attenuation rate of 0.0984 per year with a correlation coefficient of only 80%. At this degradation rate and a June 2016 concentration of 7,120 ug/L, the time to achieve the MCL in well AWD-1 is estimated to be approximately 4 years.

As TCE concentrations decrease in well AWD-1, cis-1,2-DCE and VC are observed in this well (**Figure A-27**). Substantial concentrations of cis-1,2-DCE seems to be accumulating since 2009 (as high as 90,000 ug/L). The concentrations of VC have been increasing since November 2001 and peaked at a concentration of 6,950 ug/L in September 2011. The decreasing trend in TCE concentration and the increase of cis-1,2-DCE and VC concentrations are clear indications that TCE degradation is occurring in the vicinity of well AWD-1.

3.2.2.8 MW-7 (Influenced by Groundwater Extraction)

Well MW-7 is located near ICT-12A along the western edge of LHAAP-18/24, outside of the containment area. Results from January 1999 to June 2016 show an overall decreasing trend in TCE concentrations (**Figure A-28**). The analysis of the concentration data from January 1999 shows an attenuation rate of 0.134 per year with a correlation coefficient of 71%. At this degradation rate and a June 2016 concentration of 1,740 μg/L, the time to achieve the MCL in well MW-7 is estimated to be approximately 44 years.

As TCE concentrations decrease in well MW-7, the detection of cis-1,2-DCE has been observed with one VC detection above the SQL in June 2015 at 0.322 μg/L (**Figure A29**). Cis-1,2-DCE began to appear consistently in this well since September 2001. The accumulation of cis-1,2-DCE and the absence of VC is consistent with cis-1,2-DCE stall.

3.2.2.9 MW-14 (Influenced by Groundwater Extraction)

Results from December 1996 to June 2016 show a slow decreasing trend in TCE concentration until year 9.5 (May 2006) but an increase is observed in year 13 and ensuing years (**Figure A-30**). The overall trend appears upward and the recent increase in concentration indicates that migration of CoCs from the shallow zone (vicinity of 120) to the upper Wilcox is occurring. The recent measurements indicating an increase in TCE concentration in this well were both collected after the GWTP system was down (i.e., summer of 2009 and summer of 2012).

Cis-1,2-DCE was detected as far back as 1998 and was reported in the eight most recent groundwater sampling results at 12 to 36% of the concentration of TCE (**Figure A-31**). VC was observed above the SQL in the four sampling events but at < 0.1% of TCE concentration. The appearance of cis-DCE indicates biodegradation is occurring. However, the concentration of cis-1,2-DCE in MW-14 is in line with cis-1,2-DCE concentration in 120 within the Shallow Zone which could also imply that cis-1,2-DCE in MW-14 may be sourced from the Shallow Zone. Further inspection of VC concentration in 120 indicated the presence of VC in 120 at much higher concentrations than in MW-14. Therefore, it is more plausible that cis-1,2-DCE is a result of biodegradation occurring in MW-14 (Wilcox Formation).

3.2.2.10 Monitoring Well 120 (Influenced by Groundwater Extraction)

Results from March 1998 to June 2016 show an overall slow decreasing trend in TCE concentrations (**Figure A-32**). The analysis of the concentration data from March 1998 to June 2016 shows a small attenuation rate 0.0107 per year with a correlation coefficient of 4%. The low correlation is observed because the concentration in this well fluctuates significantly. At this degradation rate and a June 2016 concentration of 17,100 μg/L, the time to achieve the MCL in well 120 is estimated to be more than 760 years. Although an attenuation rate was calculated, the severe fluctuation in concentration of TCE in this well precludes any reasonable conclusion to be drawn about concentration trends.

Cis-1,2-DCE was observed in this well since September 2008 at concentrations exceeding 2,000 μg/L (**Figure A-33**). VC was observed as back as May 2002 but only since May 2006 that VC concentration began to accumulate and reached a high of 336 ug/L in December 2013. Even though well 120 is located approximately 80 ft from ICT-12E, well 120 concentration data do

not show evidence of the potential influence of groundwater extraction as the TCE concentration is nearly unattenuated.

3.2.2.11 MW-23 (Influenced by Groundwater Extraction)

Results from January 1999 to June 2016 show an overall decreasing trend in TCE concentration (**Figure A-34**). Analysis of the concentration data shows an attenuation rate of 0.0185 per year with a correlation coefficient of 6.9%. At this degradation rate and a TCE concentration in June 2016 of 1,170 μg/L, the time to achieve the MCL in well MW-23 is estimated to be 295 years. Because no extraction occurred for the past 8 years adjacent to this well, the decreasing trend implies that TCE is naturally attenuating, although large swings in TCE concentrations is observed.

Cis-1,2-DCE was observed in this well since September 2008 at concentrations near 5 μg/L with very slight increase over time. VC was observed in May 2006, November 2009, December 2013, December 2014, and June 2015 but only at a concentration of about 1 μg/L or less. Therefore, the evidence for biodegradation in this well is not strong.

3.2.2.12 18WW08 (Not Influenced by Groundwater Extraction)

Results from November 2002 to June 2016 show a decreasing trend in TCE concentration (**Figure A-36**). Analysis of the concentration data shows an attenuation rate of 0.2345 per year with a correlation coefficient of 31.5%. The concentration in 18WW08 was < 0.5 ug/L in June 2016. This well is located in the northwest outside the direct influence of groundwater extraction but under the influence of Harrison Bayou. The decrease in TCE concentration in this well is certainly due to NA mechanisms. Therefore NA in the northeast of the site appears to be active.

Figure A-37 provides concentration profile for TCE, cis-1,2-DCE, and VC. Both cis-1,2-DCE and VC are detected in this well sporadically at low concentrations. However, since TCE concentration in this well is very low, with recent maximum concentration less than 10 ug/L, the presence of cis-1,2-DCE and VC indicates that attenuation is proportionally occurring in this well. TCE decreasing trend and observation of presence of attenuation in this well agree with the observation made for perchlorate. The absence of degrading bacteria or expressive gene to degrade TCE in this well is likely due to the non-detect or near non-detect levels of TCE observed in this well to support active biodegradation.

3.2.2.13 MW-8 (Not Influenced by Groundwater Extraction)

Results from March 1998 to June 2016 show a decreasing trend in TCE concentration (**Figure A-38**). Analysis of the concentration data shows an attenuation rate of 0.1269 per year with a correlation coefficient of 80%. At this degradation rate and a June 2016 concentration of 247 μg/L, the time to achieve the MCL in well MW-8 is estimated to be approximately 31 years. This well is located to the southwest outside the direct influence of groundwater extraction. The decrease in TCE concentration in this well is certainly due to natural attenuation mechanisms. The opposite was observed for perchlorate where the trend is upward. Perchlorate concentration in this well is also two orders of magnitude greater than TCE concentration.

Figure A-39 provides a concentration profile for TCE, cis-1,2-DCE, and VC. Cis-1,2-DCE but not VC is detected in this well at low concentrations, at a ratio of almost 1 to 100 of the TCE

concentration. Cis-1,2-DCE has a downward concentration trend is similar to TCE. Although degrading bacteria and expressive gene were not detected in this well, the presence of a TCE daughter product indicate some biodegradation is occurring in this well in addition to other attenuation mechanisms.

3.2.2.14 Summary of TCE Concentration vs. Time Analysis

The evaluation of changes in TCE concentrations with time has shown evidence of the occurrence of attenuation. The presence of TCE daughter products, cis 1,2-DCE and VC, are strong indicators supporting the occurrence of biodegradation at LHAAP-18/24.

Of the analyzed wells, MW-1, MW-2, MW-4, MW-5, MW-7, MW-08, MW-23, AWD-1, 18WW08, and MW-8 show a decreasing trend in TCE concentrations with selective accumulation of cis-1,2-DCE and VC in several wells. Wells MW-21 and 109 show an increasing TCE concentration trend while 120 exhibited a marginally decreasing trend with large concentration fluctuations likely influenced by extraction in ICT-12E. MW-14 in the Wilcox formation shows an increasing trend as represented by several recent values.

The results of TCE and perchlorate in MW-14 indicate that a closer look at this well is warranted to prevent further contamination of the Wilcox Formation in this area of the site where the clay layer is absent. Maintenance of extraction at ICT-12E and ICT-13A is important to create and maintain an upward gradient in this area of the site.

3.2.3 Methylene Chloride

MC distribution in the Shallow Zone reflects a high concentration (21,300 µg/L in June 2016) in well MW-2 with decreasing concentrations away from this location. Another area of detection of MC but at much lower concentrations occurs in the western corner of the site with the highest concentration reported in monitoring well AWD-1 at 95.1 ug/L in June 2016 (**Figure 1-13,** main text). The general trend of MC in the Shallow Zone indicates that the MC plume is very well contained in the vicinity of wells MW-2 and well 120/AWD-1.

Changes in MC concentrations not attributable to the operation of the groundwater extraction system are best indication of NA. The following reviews concentration trends of MC in various wells. Because MC is present in fewer wells than perchlorate and TCE, fewer wells are reviewed.

3.2.3.1 MW-2 (Influenced by Groundwater Extraction)

Results from May 2003 to June 2016 show a decreasing trend (**Figure A-40**). The analysis of the concentration data from May 2003 to June 2016 shows an attenuation rate of 0.227 per year with a correlation coefficient of 23%. MW-2 is located within an MC source area and the concentration in MW-2 has always been very high with implied presence of DNAPL in this well, although a decreasing trend by 1 to 3 orders of magnitude was observed in the past 12 months. At the attenuation rate observed and a June 2016 concentration of 21,300 µg/L, the time to achieve the MCL for MC (5 µg/L) in well MW-2 is estimated to be 37 years

3.2.3.2 MW-1 (Influenced by Groundwater Extraction)

Analytical data from December 1996 to June 2016 show a decreasing trend in MC concentrations (**Figure A-41**). The analysis of the concentration data from December 1996 to June 2016 shows an attenuation rate of 0.7013 per year with a correlation coefficient of 89%. The most recent concentration of MC in MW-1 is <0.5 ug/L, which is lower than the MCL.

3.2.3.3 MW-21 (Influenced by Groundwater Extraction)

Results from May 1998 to June 2016 show steady decreasing trend in MC concentrations in well MW-21 (**Figure A-42)**. The analysis of the concentration data from May 1998 to June 2016 shows an attenuation rate of 0.603 per year with a correlation coefficient of 84%. The concentration in June 2016 was < 25 μg/L (12.5 μg/L or one-half this value was listed on **Figure A-42**). At this attenuation rate and an assumed concentration of 12.5 μg/L, the time to achieve the MCL for MC in well MW-21 is estimated to be approximately 1.5 years.

3.2.3.4 AWD-1 (Influenced by Groundwater Extraction)

Analytical data from April 1994 to June 2016 show a decreasing trend in MC concentrations (**Figure A-43**). The analysis of the concentration data from December 1996 to June 2016 shows an attenuation rate of 0.2474 per year with a correlation coefficient of 50%. At this degradation rate at a June 2016 concentration of 95.1 ug/L, the time to achieve the MCL for MC in well AWD-1 is estimated to be approximately 12 years.

3.2.3.5 120 (Influenced by Groundwater Extraction)

Results from March 1998 to June 2016 show a decreasing trend in MC concentrations in well 120 (**Figure A-44**). The analysis of the concentration data from March 1998 to June 2016 shows an attenuation rate of 0.4809 per year with a correlation coefficient of 85%. The concentration in June 2016 was < 50 μg/L (25 μg/L or one-half this value was listed on **Figure A-44**). At this degradation rate and an assumed initial concentration of 25 μg/L, the time to achieve the MCL for MC in well 120 is estimated to be approximately 3.3 years.

3.2.3.6 Summary of MC Concentration vs. Time Analysis

The evaluation of changes in MC concentrations with time has shown strong evidence of the occurrence of attenuation in many wells including MW-2.

3.3 Summary and Conclusion

Table A-2 presents a summary of the trend analysis findings and presents comments associated with these findings.

Table A-2: Trend Analysis Summary

Monitoring Well	Chemical	Trend w/ Rate Constant	Finding Analysis
MW-2	Perchlorate	Downward/0.331 per year @ R^2 = 42%	MW-2 could be influenced by extraction from ICT8. MW-2 contained very high concentrations of MC at DNAPL levels; however a rapid decrease in MC concentration in MW-2 was observed since December 2015. This decrease is sudden and warrants additional data collection for verification. The observed decrease in perchlorate, TCE, and MC is small with half-lives of 2 years, 4.5 years, and 3 years and durations of 2.1, 53, and 37 years to achieve the PCL for perchlorate and the MCLs for TCE and MC. Low correlation coefficients indicate a weak trend. The presence of cis-1,2-DCE indicates biodegradation of TCE is occurring. Attenuation in the vicinity of MW-2 is higher for perchlorate than for TCE and MC.
	TCE	Downward/0.1532 per year @ R^2 = 42%	
	MC	Downward/0.227 per year @ R^2 = 23%	
MW-1	Perchlorate	Downward/0.0775 per year @ R^2 = 37%	MW-2 could have been influenced by injection in ICT6. MW-1 shows downward trends for all three chemicals with relatively high correlations for TCE and MC but a low correlation and low attenuation rate for perchlorate. The half-lives are 9, 5.8, and 0.99 years for perchlorate, TCE, and MC, respectively and durations of 87 and 55 years to achieve the PCL for perchlorate and MCL for TCE. MC concentration is already below the MCL in this well. The low correlation coefficient for perchlorate indicates a weak trend. The presence of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring. Attenuation in the vicinity of MW-1 is occurring for TCE and MC but is not important for perchlorate.
	TCE	Downward/0.1204 per year @ R^2 = 60%	
	MC	Downward/0.7013 per year @ R^2 = 89%	
MW-4	Perchlorate	Downward/0.0701 per year @ R^2 = 20%	MW-4 could be influenced by extraction from ICT14A. MW-4 shows downward trends for perchlorate and TCE only. The half-lives are 10 and 5.6 years and durations of 94 and 29 years to achieve the PCL and MCL for perchlorate and TCE, respectively. MC concentration is already below the MCL in this well. The low correlation coefficient for perchlorate indicates a weak trend. The presence of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring. Attenuation in the vicinity of MW-4 is more important for TCE but not for perchlorate.
	TCE	Downward/0.124 per year @ R^2 = 45%	
	MC	No MC detected in this well.	
MW-5	Perchlorate	Slightly increasing trend	MW-5 could be influenced by extraction from ICT7 and ICT13E. MW-5 shows a downward trend for TCE but an increasing trend for perchlorate. The half-life for TCE is 66 years and the duration to achieve the MCL is 227 years. MC concentration is already below the MCL in this well. The low correlation coefficient for TCE indicates a weak trend. The presence of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring. Attenuation in the vicinity of MW-5 is not occurring for perchlorate and it is not important for TCE.
	TCE	Downward/0.0105 per year @ R^2 = 1.4%	
	MC	No MC detected in this well.	

Monitoring Well	Chemical	Trend w/ Rate Constant	Finding Analysis
MW-21	Perchlorate	Increasing trend	MW-21 could be influenced by extraction from ICT14D. MW-21 shows a downward trend for MC but an increasing trend for perchlorate and TCE. The half-life for MC is 1.15 years. The concentration in MW-21 for MC is < 25 µg/L but a concentration of 12.5 µg/L is used to determine duration to achieve the MCL. The duration to achieve the MCL is 1.5 years. The high correlation coefficient for MC indicates a strong downward trend. The presence of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring. Attenuation in the vicinity of MW-21 is substantial for MC but not occurring for either perchlorate or TCE.
	TCE	Increasing overall trend.	
	MC	Downward/0.6026 per year @ R^2 = 84%	
109	Perchlorate	Downward/0.0817 per year @ R^2 = 20%	109 could be influenced by extraction from ICT14B and ICT14C. 109 shows a downward trend for perchlorate but an increasing trend for TCE. The half-life for perchlorate is 8.5 years and the duration to achieve the PCL is 57 years. The poor correlation coefficient for perchlorate indicates a weak downward trend. The presence of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring, although the overall trend is upward. Attenuation in the vicinity of 109 is not important for perchlorate and not occurring for TCE.
	TCE	Increasing overall trend.	
	MC	No MC detected in this well.	
AWD-1	Perchlorate	Downward/0.5169 per year @ R^2 = 66%	AWD-1 could be influenced by extraction from ICT12E. AWD-1 shows a downward trend for all three chemicals. The half-lives for perchlorate, TCE, and MC are 1.34, 7, and 2.8 years, respectively. Monitor well AWD-1 is already below the PCL for perchlorate but will take 74 and 12 years, respectively to achieve the MCLs for TCE and MC. Good correlation for TCE and MC is observed. The presence of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring. Attenuation in the vicinity of AWD-1 is less important for TCE compared to perchlorate and MC.
	TCE	Downward/0.09848 per year @ R^2 = 80%	
	MC	Downward/0.2474 per year @ R^2 = 50%	
MW-7	Perchlorate	Downward/0.0958 per year @ R^2 = 65%	MW-7 is unlikely influenced by extraction from ICT12B due to the presence of a liner. MW-7 shows a downward trend for perchlorate and TCE. The half-lives for perchlorate and TCE are 7.2 and 5.2, respectively. Monitor well MW-7 is already below the MCL for MC but will take 75 and 44 years, respectively to achieve the MCL for TCE and the PCL for perchlorate. The correlation coefficients for perchlorate and TCE indicate a reasonable downward trend for these chemicals. The presence of cis-1,2-DCE indicates biodegradation of TCE is occurring. Attenuation in the vicinity of MW-7 is somewhat important for perchlorate or TCE.
	TCE	Downward/0.134 per year @ R^2 = 71%	
	MC	Generally no MC detected in this well.	
MW-14	Perchlorate	Upward trend overall	MW-14 could be influenced by extraction from ICT12E. No trend analysis conducted for perchlorate or TCE due to a recent increase in concentrations in MW-14. Monitor well MW-14 is already below the MCL for MC, although June
	TCE	Upward trend overall	

Monitoring Well	Chemical	Trend w/ Rate Constant	Finding Analysis
MW-14	MC	MC below cleanup level, although June 2016 concentration was reported at 53.5 J µg/L.	2016 concentration was reported at 53.5 J µg/L. The presence of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring. Attenuation in the vicinity of MW-14 is not important for perchlorate or TCE.
120	Perchlorate	Downward/0.0421 per year @ R^2 = 13%	120 could be influenced by extraction from ICT12E. 120 shows a downward trend for perchlorate, TCE, and MC. The half-lives for perchlorate, TCE, and MC are 16.5, 65, and 1.44, respectively. It will take 180, 761, and 3.3 years, respectively to achieve the PCL for perchlorate, and the MCLs for TCE and MC. The correlation coefficients for perchlorate and TCE are very poor indicating a very weak downward trend. The correlation coefficient for MC indicates a reasonable downward trend. The presence of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring. Attenuation in the vicinity of 120 is not important for perchlorate or TCE but is important for MC.
	TCE	Downward/0.0107 per year @ R^2 = 4%	
	MC	Downward/0.4809 per year @ R^2 = 85%	
MW-23	Perchlorate	Upward overall trend	MW-23 is not influenced by any extraction trench. MW-23 shows a downward trend for TCE. The half-life for TCE is 37.5 years. Perchlorate trend is increasing. It will take 295 years to achieve MCL for TCE. MC is already below the MCL. The correlation coefficient for TCE is poor indicating a weak downward trend. Cis-1,2-DCE and VC were rarely reported above the reporting limit indicating that biodegradation of TCE is not occurring. Attenuation in the vicinity of MW-23 is not important for perchlorate or TCE.
	TCE	Downward/0.0185 per year @ R^2 = 7%	
	MC	MC below cleanup level.	
18WW08	Perchlorate	Downward/0.6239 per year @ R^2 = 60%	18WW08 is not influenced by any extraction trench. 18WW08 shows a downward trend for perchlorate and TCE. The half-lives for perchlorate and TCE are 1.1 and 3 years, respectively. Perchlorate in most recent result is below the PCL. TCE and MC are also already below their MCLs. The correlation coefficient for TCE is poor indicating a weak downward trend. The presence of occasional detection of cis-1,2-DCE and VC indicates biodegradation of TCE is occurring. Reliance on NA (this well is not influenced by the extraction system) in the vicinity of 18WW08 is important for perchlorate, noting that perchlorate, TCE and MC are below their PCL/MCLs.
	TCE	Downward/0.2345 per year @ R^2 = 31%	
	MC	No MC detected in this well.	
MW-8	Perchlorate	Upward overall trend	MW-8 is not influenced by any extraction trench. MW-8 shows a downward trend for TCE. The half-life for TCE is 5.5 years. It will take 31 years to achieve the MCL for TCE. MC is already below the MCL. Perchlorate is showing an overall increasing trend in the presence of very high perchlorate concentrations, although the recent trend is downward. The correlation coefficient for TCE is very strong indicating a strong downward trend. The presence of cis-1,2-DCE indicates biodegradation of TCE is occurring. Reliance on natural attenuation (this well is not influenced by the extraction system) in the vicinity of MW-8 is important for TCE but not for perchlorate.
	TCE	Downward/0.1269 per year @ R^2 = 79%	
	MC	No MC detected in this well.	

The natural attenuation analysis was done for wells inside the containment area and outside the containment area.

- The wells inside the containment area are influenced by the extraction of groundwater and the trend analysis includes the influence of extraction in addition to any NA that may be occurring (e.g., identified by the presence of daughter compounds such as cis-1,2-DCE for degradation of TCE). It is believed that extraction of groundwater removes a greater mass of CoCs compared to NA mechanisms. Additional analysis is required to determine NA rates for these wells using daughter compound concentrations and compound specific isotope analysis. The findings for the wells inside the containment can be summarized as follows:
    - Perchlorate attenuation is occurring in AWD-1 and MW-7 only.
    - TCE attenuation is occurring in MW-1, MW-4, MW-7, and MW-8 only.
    - MC attenuation is occurring in MW-1, MW-21, AWD-1, and 120 only.
- Two wells outside the containment were analyzed. The results are summarized as follows:
    - NA for perchlorate is occurring appreciably in 18WW08 (MC and TCE are below the MCL in this well).
    - NA for TCE is occurring appreciably in MW-8 (MC is below the MCL in this well and perchlorate concentration is increasing).

Another important aspect for attenuation of CoCs manifests itself with the decrease in the extent of CoCs in groundwater over time, particularly for MC.

Re: Draft Final Supplemental to the Updated Post-Screening Investigation Report for LHAAP-18/24, Burning Ground No. 3 and Unlined Evaporation Pond
Longhorn Army Ammunition Plant, Karnack, Texas

Dear Mr. Mayer,

The above-referenced document is being transmitted to you for your records and includes revisions based upon your comments on the Draft. In accordance with the FFA, the Draft Final will be considered Final after 30 days without further comment.

The document was prepared by AECOM on behalf of the Army as part of AECOMôs Performance Based Remediation contract for the facility. I ask that Debra Richmann, AECOMôs Project Manager, be copied on any communications related to the project.

The point of contact for this action is the undersigned. I may be contacted at 479-635-0110, or by email at rose.m.zeiler.civ@mail.mil.

Sincerely,

Rose M. Zeiler, Ph.D.
Longhorn AAP Site Manager

Responses to Comments on
Draft Supplemental to the Updated Post-Screening Investigation Report for LHAAP-18/24, Burning Ground No. 3 and Unlined Evaporation Pond
Longhorn Army Ammunition Plant, Karnack, Texas

September 2016

Reviewer: Rich Mayer, EPA

Respondent: Marwan Salameh and Debra Richmann, AECOM

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
1	viii	Third Paragraph	The text states ñThe elevated concentrations of perchlorate may represent perchlorate migrating via groundwater to this location prior to installation of the groundwater extraction system.ò EPA recommends adding that injection and irrigation has affected the groundwater flow paths on the site and there is potential for migration of the perchlorate around and below the ICT system.	E	Elevated levels of perchlorate in groundwater were present before irrigation and/or injection occurred. For example, perchlorate concentrations in nearby wells MW-7 and MW-8 were 105,000 Õg/L and 27,500 Õg/L, respectively, in May 2005; 89,400 Õg/L and 47,500 Õg/L in 2006; 37,500 Õg/L and 72,000 Õg/L in May 2013; and 22,000 Õg/L and 8,290 Õg/L in June 2016. The data demonstrate that perchlorate contamination was present before installation of the extraction system and there has been a decrease in perchlorate concentrations as a result of the operation of the groundwater extraction system. The text on page viii has been modified to incorporate these examples.	
2	vii	Delineation of Contaminated Soil	EPA recommends a statement in the paragraph that the MSC standard was used for the vadose zone soil. There were a couple of concentrations that exceeded the 7,200 mg/kg MSC, but appear to be in a saturated zone.	C	Text was added to page viii to specify vadose zone and saturated zone perchlorate concentrations were compared to the GWP-Ind MSC of 7,200 Õg/kg.	
3		Figure 1-4	Is the southwest corner known to be LHAAP-39? If not, please remove label from figures.	C	The LHAAP-39 label was removed from figures throughout the report.	
4	3-1	Section 3.1.1, 1st Paragraph	Text indicates VOCs concentrations were mostly nondetects. Please note when EPA observed sampling of cores the sampling team often left cores out in the sun for long periods of time before collecting VOC samples from the core. During one observation, the VOC sample was not collected until almost a half hour after core extraction. EPA recommends that for further sampling the VOCs need to be collected as soon as possible and to use an EnCore sampling method to prevent loss of VOCs in soils during sampling.	C/E	Agree, the samples observed by EPA were not collected in accordance with the SOP Subsurface Soil Sampling by Split Spoon and Continuous Split Barrel Samplers from the IWWP (AECOM, 2014). This SOP states in Section 5.3.5 that to limit the possible loss of volatiles, the soil sample should be obtained as quickly as possible from the sampler. This is the protocol that is normally followed and future samples will be collected in accordance with this SOP.

Reviewer: Rich Mayer, EPA

Respondent: Marwan Salameh and Debra Richmann, AECOM

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
5	3-4	Section 3.2	EPA recommends adding an explanation on why well 18WW25 was not sampled.	E	Well 18WW25 was sampled and the results are presented in the report. The text was corrected to remove the incorrect statements that 18WW25 was not sampled in Section 3.2 and on page ix.	
6	3-4	Section 3.2.1, First Paragraph	Well MW-20 is known to be in a perched zone. The new well 18CPTMW22R appears to also be completed in that small perched zone. EPA recommends not using these wells for groundwater level contouring.	C	Section 3.2.1 text and Figure 3-1 were revised to indicate groundwater at wells MW-20 and 18CPTMW22R is perched.	
7	3-4	Section 3.2.1	How were elevations determined at the new wells since earlier in the text it is mentioned that the wells have not been surveyed?	E	The wells were surveyed. The text of Section 2.3 has been updated to include the surveying results.	
8	3-6	Top of Page	EPA agrees that the lateral extend of the perchlorate in the upper Wilcox is delineated. However vertical extend of perchlorate is not known in the northwest (1 location) and northeast corners (1 location) of the site. EPA assumes additional wells will be drilled in the future to determine vertical extend in these areas.	C	Text was added at the top of page 3-6 (Section 3.2.2.1) that provides information about the lack of vertical delineation at MW-14 and 18CPTMW08DW.	
9	3-6	Section 3.2.2.2, First Paragraph	EPA agrees for the most part that the TCE in the shallow zone is delineated; however, MW-18 to the west had a detection of 14.1 which is still above the MCL. EPA recommends mentioning this detection in text. Newly planned activities at LHAAP-17 may help delineate the plume (just a little further to the west). One note, figure 2-2 in the LHAAP-17 report shows a 2009 sample collected at MW-18 and it was a nondetect. The recent result may indicate that the TCE plume is expanding.	C/D	Text was added to Section 3.2.2.2, Section 4.1, and page X discussing detection of TCE in MW-18. TCE has been detected historically in MW-18 above the MCL/PCL. Examples include 100 µg/L in May 2000 and 17 µg/L in December 1996. Therefore, we do not believe the TCE plume is necessarily expanding in this area.

Respondent: Marwan Salameh and Debra Richmann, AECOM

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
10	3-7	First Paragraph	Please define PCL in text and add to acronym list.	C/D	Added definition of PCL in the text in Section 3.2.2.4. PCL and TRRP are included and defined in the acronym list.	
11		Table 3-4	Please update table 3-3 with new well elevations, since it appears this table contains the data needed.	C	Table 3-3 was updated with surveying data.	
12	4-2	Number 13	Please see comment 9 above.	C	Please see response to comment 9.	
13	4-3	Second Bullet	This sentence seems awkward. One can say that these areas do not appear to be a source of perchlorate for Site 17. EPA assumes the intent might be that perchlorate is not migrating via the groundwater towards Site 17. Additional investigations at Site 17 may determine if there are comingling plumes from the two sites.	C/D	The intent of the second bullet is that perchlorate is not migrating via groundwater to site 17 from 18/24. We do not believe there are commingled plumes from site 17 and site 18/24 because perchlorate concentrations in 18CPTMW26, 18CPTMW26SW, and 18DP08 located between the two sites were very low or non-detectable. Text was added to the second bullet to clarify the sentence.	
14	4-3	Fourth Bullet	EPA agrees that the lateral extent of the COCs is mostly defined. However, the vertical extent has not been determined in few locations (i.e. MW-14 and 18CPTMW08DW).	C	Text added to the fourth bullet that indicates where delineation is not complete.	
15	4-3	Fifth Bullet	EPA recommends deleting this bullet. The previous bullet makes the same statement.	C	The fifth bullet removed from Section 4.2.

1. Respondent Concurs (C), Does Not Concur (D), Takes Exception (E), or Delete (X).
2. Commentor Agrees (A) with response, or Does not Agree (D) with response.

Comment #	Page	Section/ Paragraph	Comment	C, D, E or X[1]	Response	A or D[2]
1		18CPTMW22 Replacement pages	This log is really difficult to get meaningful information out of. The log should be redone from scratch. A note could be included to indicate the log replaces previous version in the other report.	C	A new log was created that shows the correct well construction information with a note that clarifies the new log is a revision. The original log will remain included for recordkeeping purposes, but an ñXò is put through the log to make it clear the log is no longer valid.	
2		Relevant to that log	Could you also please revise the cross section from the other PSI report for D-Dô to indicate the actual screen interval from 18CPTMW22. It would be very helpful to also include the 18CPTMW22 well logs (SW and DW) in this cross section. A note could be included to indicate the cross-section replaces previous version in the other report.	C	Cross-section D-Dô is updated by correcting the well screen for 18CPTMW22 and adding logs for 18CPTM22SW/DW. A new Section 3.3 was added to the report referencing cross-section D-Dô and indicating that it replaces a previous version in the Updated PSI report (Feb 2016).	
3	1-3	Section 3.2.1 Groundwater elevation discussion	It is my understanding that the new wells were not surveyed at the time of writing. This narrative should include notes to indicate interpretation could change based on survey elevations, especially when discussing slight upward or downward gradients.	E	All new wells were surveyed. Section 2.3 has been updated by providing survey information for the new wells and borings. Accordingly, no changes are needed for Section 3.2.1.	
4		All relevant figures (groundwater potentiometric) and Table 3-4	Should have notes regarding new wells not surveyed.	E	Please see response to comment #3.	
5		Figure 3-1	MW-20 and 18CPTMW22R have comparable groundwater elevations. It is still relevant to discard MW-20 as a data point? If so, shouldnôt the new well also be discarded?	C	Section 3.2.1 text and Figure 3-1 were revised to indicate groundwater at wells MW-20 and 18CPTMW22R is perched, and groundwater elevations in MW-20 and 18CPTMW22R were not used in contouring the Shallow Zone groundwater surface.

EXECUTIVE SUMMARY

This Supplemental to the Updated Post-Screening Investigation (PSI) Report was prepared on behalf of the United States (U.S.) Army Corps of Engineers (USACE) for sites LHAAP-18 (Burning Ground No. 3) and LHAAP-24 (Unlined Evaporation Pond [UEP]/Rocket Motor Washout Facility) at the former Longhorn Army Ammunition Plant (LHAAP) in Karnack, Texas. The purpose of this report is to summarize the results of the environmental investigations conducted at LHAAP-18/24 by AECOM Technical Services, Inc. (AECOM) between February 2016 and June 2016. This information will be used to fill data gaps identified in the Updated Post-Screening Investigation (PSI) Report for LHAAP-18/24 (AECOM, 2016), to respond to comments from the U.S. Environmental Protection Agency (USEPA) and the Texas Commission on Environmental Quality (TCEQ) on the PSI report, and to complete a Revised Feasibility Study (FS) for LHAAP-18/24 that includes evaluation of contingency remedies for 1,4-dioxane.

The investigation work and the information presented in this report are based on the LHAAP-18/24 Supplemental PSI Work Plan (WP) (AECOM, 2015) that was developed by AECOM on behalf of the U.S. Department of the Army (U.S. Army). The WP was reviewed by and concurrence was received from the TCEQ and the USEPA.

Background

LHAAP-18/24 is a 34.5 acre fenced, cleared area located in the southeastern section of LHAAP. The area was used for the treatment, storage, and disposal of solid and liquid explosive, pyrotechnic, and combustible solvent waste by open burning/open detonation, incineration, evaporation, and burial. Burning Ground No. 3 operated between 1955 and 1998. Historical waste management units include open burn pits, the UEP, stockpiles of solvent-soaked sawdust, an air curtain destructor (ACD), and suspected waste burial pits. A groundwater extraction system incorporating approximately 5,000 feet (ft) of interceptor-collection trenches (ICTs) and a groundwater treatment plant (GWTP) was installed in 1997 to control the migration of contaminated groundwater. The area within the ICTs is considered the containment area.

Field Investigation Scope of Work

The purpose of this investigation was to provide better definition of the presence and extent of contamination in soil and groundwater within specific areas of the site, as discussed below.

The following specific objectives were identified for this work:

- Assess the extent of the potential perchlorate source in the southern corner of the site
    - Determine the presence and extent of a potential perchlorate source in the Shallow Zone soil and groundwater in the vicinity of MW-7 extending south toward 18CPTMW22SW.
    - Determine if perchlorate in Shallow Zone groundwater extends from LHAAP-18/24 to LHAAP-17 in the southern part of LHAAP-18/24.
- Delineate perchlorate in specific groundwater areas where data gaps were identified in the Updated PSI report (AECOM, 2016). These areas include the southern portion of the site near 18CPTMW22SW; the northwest area in the vicinity of 18CPTMW23 and near Harrison Bayou; and in proximity to 18CPTMW19.

To achieve these objectives, vertical soil profiling of perchlorate and volatile organic compound (VOC) concentrations was conducted utilizing direct push technology (DPT), sonic, and hollow stem auger (HSA) drilling methods to recover soil cores. Soil samples from each soil boring were obtained at approximately 10 foot intervals from the ground surface to borehole terminus. Lateral extent of contamination in the Shallow Zone was also determined from the samples collected from the DPT borings.

Delineation of Contaminated Soil

The scope of work included advancing DPT borings and collecting soil samples from up to 30 soil borings as deep as 45 ft below ground surface (bgs) in the southern corner of the site in proximity of MW-7 and 18CPTMW22SW. Five initial soil borings were advanced around 18CPTMW22SW, which is the location of known high perchlorate concentrations in the saturated soil and groundwater. Based on the analytical results from the initial borings, step out borings were advanced at progressively greater distances from the impacted initial soil borings until concentrations of perchlorate and VOCs were below levels protective of groundwater GWP-Ind Medium Specifc Concentration (MSC) of 7,200 micrograms per kilogram (Õg/kg) for perchlorate and 100 times the Maximum Contaminant Level (MCL) for VOCs. The GWP-Ind MSC for perchlorate was used for both saturated and vadose zone soil samples. Using this approach for delineating the lateral extent of contamination, a total of 17 shallow soil borings were advanced and sampled.

Shallow Zone Groundwater Monitoring Wells

The scope of work for Shallow Zone groundwater included the following activities:

- Installation of a 4-inch diameter monitoring well to replace former monitoring well 18CPTMW22, including vertical soil profiling for perchlorate and VOCs in the Shallow Zone and Wilcox clay.
- Installation of a 4-inch diameter monitoring well approximately 250 ft west/southwest of former monitoring well 18CPTMW22 for delineation of perchlorate extent in the direction of LHAAP-17. Vertical soil profiling for perchlorate and VOCs in the Shallow Zone and Wilcox clay was also performed.
- Installation of a 4-inch diameter monitoring well approximately 100 ft north of monitoring well 18CPTMW23 for delineation of perchlorate extent toward Harrison Bayou. Vertical soil profiling for perchlorate and VOCs in the Shallow Zone formation and Wilcox clay was also performed.

Wilcox Formation Groundwater Monitoring Wells

The scope of work for Wilcox Formation groundwater included the following activities:

- Installation of a deep Wilcox 4-inch diameter monitoring well in proximity of monitoring well 18CPTMW22SW, and vertical soil profiling for perchlorate and VOCs in the Wilcox Clay and Wilcox Formation.
- Installation of a 4-inch monitoring well adjacent to monitoring well 18CPTMW23 for lateral and vertical perchlorate and VOCs delineation in the Wilcox Formation. The work included completion of vertical soil profiling for perchlorate and VOCs in the Shallow

Zone and upper Wilcox Formation. This well was installed deeper than 18CPTMW23 in a clean soil interval in the Wilcox Formation.

- Installation of an upper Wilcox 4-inch diameter monitoring well approximately 100 ft north of monitoring well 18CPTMW08SW and adjacent to 18CPTMW19 for vertical and lateral delineation of perchlorate and VOCs. Vertical soil profiling for perchlorate and VOCs in the Wilcox Formation was also performed.
- Installation of an upper Wilcox 4-inch diameter monitoring well approximately 250 ft west/southwest of former monitoring well 18CPTMW22 for perchlorate delineation toward LHAAP-17. Vertical soil profiling for perchlorate and VOCs (combined with the Shallow Zone soil profiling discussed above) into the upper Wilcox Formation.

The Revised Updated PSI Addendum field investigation was initiated using a DPT rig between February 22 and March 15, 2016 for perchlorate assessment in the Shallow Zone of the southern portion of the site. Between April 18, 2016 and June 27, 2016, seven additional monitoring wells were installed, four of which are located in the southern portion as part of the perchlorate assessment. Three of the monitoring wells, 18CPTMW23SW, 18WW24, and 18CPTMW19SW, were installed on the north side of the site beyond the containment area to complete the delineation of perchlorate in this area of the site.

Seventeen shallow soil borings were advanced using DPT in the southern corner of the site for perchlorate delineation, soil characterization, and soil sampling. In this report, the Shallow Zone is defined as the unsaturated and saturated soil from the ground surface to a depth of up to 45 ft bgs, which typically overlies a clay layer (identified as the Wilcox clay) that separates the Shallow Zone (alluvial deposits) from groundwater in the Wilcox Formation.

Three monitoring wells were installed in the Shallow Zone to an approximate depth of 35 ft bgs, three wells were installed in the Intermediate Zone to an approximate depth of 65 ft bgs, and one well was installed in the Deep Zone to an approximate depth of 90 ft bgs. Six of the borings for the monitoring wells were drilled using sonic drilling techniques and one shallow well boring was drilled using an HSA drill rig. The shallow wells were completed in the Shallow Zone groundwater. The intermediate wells were completed in the upper Wilcox and the deep well was completed in the lower Wilcox.

Temporary steel surface casing was used to isolate the deeper groundwater (Intermediate and Deep Zones) from the Shallow Zone groundwater to reduce the potential for cross contamination. Discrete soil samples were obtained from the monitoring well boreholes at intervals up to approximately 10 ft for vertical profiling of perchlorate and VOCs.

Field Investigation Findings

Southern Corner of Site

High perchlorate concentrations were identified in the Shallow Zone and upper Wilcox Formation in wells 18CPTMW22 and 18CPTMW22SW in the area just outside the southern corner of the site; however, the source of this perchlorate is unknown. Therefore, this additional soil investigation in the southern corner of the site was conducted to further determine the presence and source of perchlorate in this area of the site. Eighty-five discrete soil samples from 17 DPT soil borings were collected in the Shallow Zone. In addition, 25 discrete soil samples (12

from the Shallow Zone and 13 from the Wilcox Formation) were obtained from the boreholes of four monitoring wells outside the southern corner of the site.

The perchlorate concentrations in the vadose zone in the six DPT boreholes collected inside the containment area in the southern portion of the site revealed low to nondetectable concentrations of perchlorate, with the highest concentration found in 18DPT04 at 5-5.5 ft bgs at 101 Õg/kg, located adjacent to the former building X-25. These perchlorate concentrations are less than the GWP-Ind MSC of 7,200 Õg/kg used for the vadose zone soil. In the saturated zone inside the containment area, the concentration of perchlorate was elevated particularly in the Wilcox clay. The highest concentration of perchlorate in the Wilcox Clay was detected in 18DPT04 at 36.5-37.0 ft bgs at 3,200 Õg/kg. These perchlorate concentrations however are still less than the GWP-Ind MSC of 7,200 Õg/kg, which was used for perchlorate in saturated soil. Therefore, there is no particular source of perchlorate identified in the Shallow Zone (vadose and saturated) in this area of the site.

Outside the southern corner of the site, the concentration of perchlorate in the vadose zone ranged from low (5.53 Õg/kg) to nondetect. The low to nondetectable concentrations of perchlorate in the vadose zone would indicate that perchlorate is not sourced from a surface release in this area.

In the saturated Shallow Zone, the concentrations of perchlorate were typically low increasing in depth the closer the samples were to the Wilcox clay. The higher concentrations of perchlorate in the shallow saturated zone were detected in 18DPT03 (3,290 Õg/kg at 14.5-15 ft bgs) , 18DPT15 (3,440 Õg/kg at 21-21.5 ft bgs), and 18DPT11 (3,940 Õg/kg at 20-20.5 ft bgs). These concentrations of perchlorate were found in the coarser materials (sand) just above the Wilcox clay. The highest perchlorate concentrations in the Wilcox clay were detected above the GWP-Ind MSC of 7,200 Õg/kg in the borehole of monitoring well 18CPTMW22DW at 9,440 Õg/kg at 29.5-30 ft bgs and in 18DPT12 at 15,900 Õg/kg at 18-18.5 ft bgs. These samples were collected from saturated soils. The elevated concentrations of perchlorate in the Wilcox clay may represent perchlorate migrating via groundwater to this location prior to installation of the groundwater extraction system. For example, perchlorate concentrations in nearby wells MW-7 and MW-8 were 105,000 Õg/L and 27,500 Õg/L, respectively, in May 2005; 89,400 Õg/L, and 47,500 Õg/L in 2006; 37,500 Õg/L and 72,000 Õg/L in May 2013; and 22,000 Õg/L and 8,290 Õg/L in June 2016. These data demonstrate that perchlorate contamination was present before installation of the extraction system and there has been a decrease in perchlorate concentrations as a result of the operation of the groundwater extraction system.

Perchlorate concentrations for the 18CPTMW22 stepout borings were considerably lower or nondetect. Therefore, using a perchlorate GWP-Ind MSC of 7,200 Õg/kg for industrial land use scenario, these low or nondetect perchlorate concentrations provide delineation of extent of perchlorate in the vadose and saturated zones of the Shallow Zone and indicate that a source does not exist in this area of the site.

Data Gaps Northwest of the Containment Area

Other locations where data gaps were identified include northwest of the site in proximity to 18CPTMW19, in proximity to 18CPTMW23, and farther to the northwest from 18CPTMW23 adjacent to Harrison Bayou. To address the data gaps identified at these locations, soil samples from the following boreholes were analyzed to delineate the perchlorate impact:

- 18CPTMW19SW – perchlorate concentrations were below the detection limits at 5-5.5 ft bgs and 10-10.5 ft bgs. At 20-20.5 ft bgs 8.74 µg/kg was detected followed by no detections at 30-30.5 ft bgs. At 40-40.5 and 50-50.5 perchlorate was detected at 124 µg/kg and 170 µg/kg, followed by no detections at 60-61 ft bgs. Saturation at this location was encountered at approximately 10 ft bgs. The Wilcox clay appears to extend from 20.3 ft bgs to 41.4 ft bgs.
- 18CPTMW23SW – relatively low concentrations of perchlorate were detected at 5-5.5 ft bgs, 10-10.5 ft bgs and 20-20.5 ft bgs at 19.6 µg/kg, 1,920 µg/kg, and 29.3 µg/kg, respectively. At depths of 30-30.4 ft bgs, 40-40.5 ft bgs, 50-50.5 ft bgs, and 60-60.5 ft bgs perchlorate concentrations were below the detection limits. Saturated conditions were observed at the surface and throughout the borehole as the area had previously been subjected to flooding due to heavy rains. The Wilcox clay was not identified at this location.
- 18WW25 near Harrison Bayou – no perchlorate was detected in any of the analyzed soil samples at 3.5-4 ft bgs 9.5-10 ft bgs 14.5-15 ft bgs, 19.5-20 ft bgs, 22-22.5 ft bgs. Saturation at this location was encountered at approximately 2 ft bgs during drilling. The Wilcox clay was not identified.

Groundwater Results

A comprehensive sampling event for groundwater was conducted in June 2016 after the monitoring wells were installed. A comprehensive groundwater level gauging event was conducted on June 9, 2016, except for monitoring well 18WW25, which was not installed until June 27, 2016, after the gauging event (well 18WW25 was however sampled on June 29, 2016 and analyzed for COCs). The Shallow Zone groundwater potentiometric results indicate the presence of a localized groundwater high in the northern portion of the site near monitoring wells AWD-1 and 123, as has been observed historically. The new monitoring well 18CPTMW22R, just outside the containment area to the south of the site, indicated the presence of a groundwater high. The Wilcox Formation potentiometric results indicate the presence of a groundwater high in the vicinity of MW-14 in the northwest area of the site, consistent with previous observations.

Shallow Zone monitoring well 18CPTMW26 had insufficient amount of water and was not sampled. Shallow Zone monitoring well 18CPTMW22R to the south of the site, which is screened between 4.8 ft bgs and 14.3 ft bgs, had a perchlorate concentration of 0.917 µg/L. The low perchlorate concentration in the groundwater corroborates the < 2.8 µg/kg of perchlorate in the soil samples collected at this location to a depth of 15.5 ft bgs. This low perchlorate result in 18CPTMW22R contrasts with the high perchlorate concentration in plugged Shallow Zone well 18CPTMW22, which had perchlorate of 106,000 µg/L in June 2014. Shallow Zone well 18CPTMW22 was screened between 19 and 28 ft bgs through a highly impacted Wilcox clay zone. Soil samples from 18CPTMW22DW drilled in April 2016 indicated the presence of perchlorate at 5,400 µg/kg at a depth of 20 to 20.5 ft bgs. Soil samples collected from 18CPTMW22SW had perchlorate concentrations of 10,600 µg/kg at a depth of 24 ft bgs and 10,200 µg/kg at a depth of 26.5 ft bgs. These high concentrations of perchlorate in soil across the screened interval of 18CPTMW22 coincide with the high groundwater perchlorate concentration reported in plugged well 18CPTMW22.

Perchlorate was not detected in new Shallow Zone monitoring well 18WW25 near Harrison Bayou to the northwest. Similarly, no detections of 1,4-dioxane (< 1 μg/L), TCE (< 0.5 μg/L), or MC (< 0.5 μg/L) were observed in this well. No detections of 1,4-dioxane (< 1 μg/L), TCE (< 0.5 μg/L), or MC (< 0.5 μg/L) were observed in new Shallow Zone monitoring well 18CPTMW22R.

Upper Wilcox Formation monitoring well 18CPTMW22SW, co-located with Shallow Zone well 18CPTMW22R and Lower Wilcox Formation well 18CPTMW22DW had a perchlorate concentration of 10,200 μg/L, a methylene chloride concentration of 0.534 J μg/L, a TCE concentration of 0.633 J μg/L, and a 1,4-dioxane concentration of < 0.5 μg/L. Monitoring well 18CPTMW26SW had a perchlorate concentration of 6.42 μg/L but no detections of 1,4-dioxane (< 1 μg/L), TCE (< 0.5 μg/L), or MC (< 0.5 μg/L). This well is located between LHAAP-18/24 and LHAAP-17 and indicates that little migration of perchlorate has occurred toward this location.

New upper Wilcox Formation wells, 18CPTMW19SW and 18CPTMW23SW, located in the northwest of the containment had no detection of 1,4-dioxane (< 1 μg/L), TCE (< 0.5 μg/L), or MC (< 0.5 μg/L) and low concentrations of perchlorate (1.25 μg/L in 18CPTMW19SW and 0.407 μg/L in 18CPTMW23SW). These wells provide delineation of these constituents in the north/northwest area of the site.

In general, the lateral extent of perchlorate, TCE, MC, and 1,4-dioxane in the Shallow Zone and in the Wilcox Formation has been determined with two exceptions. 1,4-Dioxane in MW-16 near Harrison Bayou had a concentration of 18 μg/L, exceeding the 1,4-dioxane Groundwater Residential Protective Concentration Level (PCL) of 9.1 μg/L. The TCE result of 14.1 μg/L at MW-18, located to the southwest of the site, exceeded the MCL of 5 μg/L.

1 INTRODUCTION

AECOM Technical Services, Inc. (AECOM) has been contracted by the USACE, Tulsa District, to complete the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Remedial Action (RA) at the Longhorn Army Ammunition (LHAAP) site LHAAP-18/24 (Burning Grounds #3 and Unlined Evaporation Pond [UEP]), located in Karnack, Texas. The U.S. Army Base Realignment and Closure (BRAC) Division received administrative control of LHAAP in October 2002. The U.S. Army Environmental Command (AEC) is responsible for funding the Installation Restoration Program (IRP) and Military Munitions Response Programs at LHAAP.

This document describes the targeted investigation activities at LHAAP-18/24 (site) to supplement the data collected under the Post-Screening Investigation (2013 investigation) (AECOM, 2013) and Updated PSI Report (2014 investigation) (AECOM, 2016). The purpose of this work is to fill data gaps at site LHAAP-18 (Burning Ground No. 3) in support of completing the Feasibility Study (FS) for the site. These data gaps were identified in the Final Updated PSI Report (AECOM, 2016), and from U. S. Environmental Protection Agency (USEPA) and Texas Commission on Environmental Quality (TCEQ) comments on the report. The scope of this work was developed during the monthly managers meeting held on October 29, 2015, documented in a Supplemental PSI Work Plan (WP) (AECOM, 2015), and approved by USEPA and TCEQ on December 21, 2015 and December 16, 2015, respectively.

1.1 LHAAP Background

The LHAAP is an inactive, government-owned, formerly contractor-operated and maintained industrial facility located in central-east Texas in the northeastern corner of Harrison County. The facility occupies approximately 1,400 of its former 8,416 acres located between State Highway 43 in Karnack, Texas, and the western shore of Caddo Lake as shown in **Figure 1-1**. LHAAP was listed as a National Priorities List site on August 9, 1990, due to threatened releases of hazardous substances, pollutants, or contaminants. The USEPA, the Texas Water Commission (now the TCEQ), and the U.S. Army signed a Federal Facilities Agreement on December 30, 1991.

The nearest cities are Marshall, Texas, approximately 14 miles to the southwest, and Shreveport, Louisiana, approximately 40 miles to the southeast.

1.2 LHAAP-18/24 Background

LHAAP-18/24 is a 34.5 acre fenced, cleared area (with an interim remedy that includes a containment area) located in the southeastern section of LHAAP (**Figure 1-2**). The site is between Avenue Q to the southeast and Harrison Bayou to the northwest. LHAAP-17 (Burning Ground No. 2) is to the southwest (**Figures 1-2** and **1-3**), and heavily wooded areas lie to the east and northeast. The area had been used for the treatment, storage, and disposal of solid and liquid explosive, pyrotechnic, and combustible solvent waste by open burning/open detonation, incineration, evaporation, and burial. LHAAP-18/24 encompasses a number of Defense Environmental Restoration Program Management Information System sites:

- Burning Ground No. 3;
- Rocket Motor Washout Pond;

- Former UEP;
- 24-X Holding Area;
- 25-X Washout Pad;
- Air Curtain Destructor;
- Three Open Burning Cages (003, 155, 156);
- Two Open Burning Pans (157, 158);
- Building 41-X; and
- Building 43-X.

The locations of these sites within LHAAP-18/24 are presented in the Environmental Site Assessment (Plexus, 2005) and identified in **Figure 1-3**. The former UEP/Rocket Motor Washout Facility is located within the northern corner of LHAAP-18/24.

LHAAP-18/24 is generally vegetated with grass and weeds and is crossed by a number of paved roads. It is situated on a natural topographic high slightly west of the crest of a small topographic divide between Harrison Bayou and Saunder's Branch. The topography of the site has been greatly altered by operations over the past 35 years. LHAAP- 18/24 is mostly level, with more relief near the western corner that contained the air-curtain destructor until 2003 and near the northern corner that contains the mounded surface of the former UEP. No signs of substantial erosion are visible.

Burning Ground No. 3 operated between 1955 and 1998. Historical waste management units include open burn pits, the UEP, stockpiles of solvent-soaked sawdust, and suspected waste burial pits. The UEP was constructed at the burning ground in 1963 as a holding pond to store explosive wastes resulting from the washout of rocket motor casings. In 1973, the pond also began receiving waste water containing solvent residues and solids. An air curtain destructor (ACD) was built in 1979 for the purpose of disposing of explosive and explosive-contaminated wastes by burning.

Use of burn pit and trenches was reportedly discontinued in 1984, and the use of the UEP was also discontinued in 1984 when it was discovered that the pond was contaminating groundwater beneath the site. The UEP was closed as a Resource Conservation and Recovery Act (RCRA) interim status surface impoundment in 1986 by removing all waste and capping the impoundment. The last burning cage was removed in 1998.

Wastes removed during the closure of the UEP were disposed of off-site at a RCRA certified disposal facility. As part of the LHAAP-18/24 Interim Remedial Action (IRA), approximately 32,000 cubic yards of source area soil were excavated and treated by low temperature thermal desorption. Some of the treated soil was placed at LHAAP-12 and LHAAP-16.

A groundwater extraction system incorporating approximately 5,000 ft of ICTs and a groundwater treatment plant (GWTP) was installed in 1997 to control the migration of contaminated groundwater in the shallow groundwater zone. The treated water is primarily planned to be released to Harrison Bayou with occasional release of treated water as irrigation water on LHAAP-18/24, or to a holding pond (INF Pond). However, due to drought conditions

between 2011 and 2014, flow in Harrison Bayou did not support discharge to Harrison Bayou. Instead, the majority of the treated water was released via irrigation.

1.2.1 Surface Water Hydrology

Harrison Bayou flows within approximately 200 ft of the western corner of LHAAP-18/24. There are no surface water bodies or watercourses running through the site. Surface drainage occurs in all directions, but flow is generally directed toward Harrison Bayou to the West and by both natural and manmade ditches and drainage swales to the north. Harrison Bayou drains into Caddo Lake, which is located approximately one mile northeast of LHAAP-18/24. The extreme western corner of the site is located within the 100-year floodplain of Harrison Bayou.

1.2.2 Hydrogeology

Until 2012, the existing Conceptual Site Model (CSM) described three groundwater zones at LHAAP-18/24: shallow, intermediate, and deep. The three groundwater zones were described as somewhat separated by non-uniform, non-contiguous clay or silty clay layers. The separation between aquifer zones is therefore primarily descriptive and defined by the intervals in which groups of monitoring wells have been completed. The depths of monitoring wells screened in the shallow groundwater zone are typically between 10 and 53 feet (ft) below ground surface (bgs). The depths of monitoring wells in the intermediate groundwater zone are typically between 44 and 80 ft bgs. The depths of monitoring wells in the deep groundwater zone are between 98 and 185 ft bgs.

The CSM was updated on October 18, 2012. The updated CSM describes the presence of two units at LHAAP-18/24: a shallow unit up to a depth of approximately 45 ft bgs (Shallow Zone), and a deep unit below the shallow zone (Wilcox Formation). Generally, these two units are separated by a contiguous clay layer which is believed to be present across the entire site with the exception of the area to the west and northwest towards Harrison Bayou (i.e., within the floodplain of Harrison Bayou). As an example, it appears that the Shallow Zone and Wilcox Formation are well separated beyond the eastern edge of the site (e.g., near 18WW17 and 18WW18), while there is no separation at all just beyond the western corner (i.e., in the vicinity of 18WW02 and 18WW06). In between, the clay layer beneath the shallow zone varies considerably in depth and thickness. Generally, based on the updated CSM, the shallow and shallow/intermediate-screened wells are identified in the Shallow Zone (up to a depth of 40 ft bgs) and the intermediate and deep-screened wells are identified in the Wilcox Formation (generally below approximately 45 ft bgs). The intermediate wells are generally screened in the upper (shallow) Wilcox Formation and the deep wells are generally screened in the lower (deep) Wilcox Formation. Upper Wilcox and shallow Wilcox are used interchangeably and refer to the portion of the Wilcox Formation just below the Wilcox clay at an approximate depth of 50 to 80 ft bgs. Similarly, lower Wilcox and deep Wilcox are used interchangeably and refer to the portion of the Wilcox Formation at approximately 80 ft or more bgs.

Figure 1-4 shows the shallow groundwater elevations for March 2016 (prior to the current investigation), indicating the groundwater flow in the shallow zone to occur outwardly from the site in a radial direction. Localized influence of groundwater extraction and reinjection can be observed in the shallow aquifer. The gradient and direction of flow in the Wilcox Formation in the northern portion of the site seem to be similar to the shallow zone; toward Harrison Bayou (**Figure 1-5**).

Groundwater in the deep zone near LHAAP is currently used as a drinking water source. As of May 2015, six active water supply wells near the LHAAP were identified (**Figure 1-2**). All these public water supply wells are located greater than two miles from the LHAAP-18/24 site. Karnack Water Supply Corporation operates two Public Water Supply Wells servicing the town of Karnack. These wells were completed in 1905 to depths of 287 and 285 ft bgs and are located hydraulically upgradient approximately one-quarter mile northwest and one-half mile southwest of the town center, respectively. Caddo Lake Water Supply Corporation operates three source wells located north and northwest of LHAAP that have been in use since 1905. These wells are hydraulically upgradient of LHAAP (Jacobs, 2002) with completion depths of 244, 185 and 310 ft bgs. Caddo Lake State Park operates one source well located approximately 1.6 miles northwest upgradient of LHAAP. This well was installed in 1905 with a total depth of 292 ft. Due to the large distance between these wells and LHAAP, water removal from these wells is not expected to affect groundwater flow at the site. In addition, there are several livestock and domestic wells (shown as Groundwater Wells on **Figure 1-2**) located in the vicinity of LHAAP with depths averaging 250 ft (**Figure 1-2**). There are three water supply wells located within LHAAP (see **Figure 1-2**) upgradient of LHAAP-18/24. These water wells supply water to buildings currently in use on the installation. Their approximate locations and depths are as follows:

- 150 ft south-southeast of the fire station approximately 2 miles from LHAAP-18/24; 128 ft deep
- İ mile southwest of the fire station approximately 2 miles from LHAAP-18/24; 195 ft deep
- At the U.S. Fish and Wildlife Service facility approximately 2.6 miles from LHAAP-18/24; 220 ft deep

None of these wells are close to LHAAP-18/24, and none of these wells are used for drinking water. Two additional wells that had previously supplied water to the installation have been plugged and abandoned. None of the water supply wells are associated with or are in imminent danger from the localized contaminated groundwater at LHAAP-18/24.

1.3 Previous Investigations and Remedial Actions

The environmental media (e.g., soil, groundwater, surface water, and sediment) at LHAAP-18/24 have been the subject of numerous investigations to identify potential contamination. Those investigations are summarized in the Updated PSI Report for LHAAP-18/24 (AECOM, 2016).

In addition to the IRAs described above, several remedial actions have been conducted at LHAAP-18/24. These are summarized in the Updated PSI Report for LHAAP-18/24 (AECOM, 2016).

1.4 Organization of Report

This report has been organized in the following sections:

- *Section 1: Introduction* - summarizes the site background including previous investigation and remediation activities, and provides the purpose, scope of work, and objectives of the WP

- *Section 2: Investigation Activities* - describes the completed scope of work and the sampling and analysis methodology to address the site data gaps. Deviations from the Supplemental PSI WP (AECOM, 2015) are presented in this Section
- *Section 3: Investigation Findings* ï provides a presentation of the data, updates to the CSM, analysis of the data gaps, and discussion of the findings
- *Section 4: Conclusions and Recommendations* ï Provides main conclusions and recommendations
- *Section 5: References* - provides a list of references cited in the document.

This Revised Updated PSI Addendum Report also includes a number of appendices supporting the main text:

- Appendix A: Field Boring Logs and Monitoring Well Construction Logs
- Appendix B: Quality Control Summary Report & Laboratory Analytical Reports.
- Appendix C: Groundwater Sampling Forms.

2 INVESTIGATION ACTIVITIES

This section presents the completed investigation scope of work, the sampling and analysis methodology, and deviations from the Supplemental PSI WP (AECOM, December 2015).

2.1 Data Gaps and Proposed Investigation Scope of Work

To address the data gaps identified in the Final Updated PSI Report (AECOM, 2016), the specific areas that were investigated are presented below.

2.1.1 Potential Perchlorate Source Extent Assessment in the Southern Corner of the Site

The following specific objectives were identified for this work:

- Determine the presence and extent of a potential perchlorate source in the Shallow Zone groundwater in the southern area of the site. This area is in the vicinity of MW-07 extending southeast to the vicinity of 18CPTMW22SW.
- Determine if perchlorate in Shallow Zone groundwater extends from LHAAP-18/24 to LHAAP-17 in the southern area of LHAAP-18/24.

2.1.2 Shallow Zone Groundwater Monitoring Wells

The scope of work in the Shallow Zone groundwater included the following activities:

- Installation of a 4-inch diameter monitoring well to replace former monitoring well 18CPTMW22, including completion of vertical soil profiling for perchlorate and volatile organic compounds (VOCs) in the shallow zone formation into the Wilcox clay.
- Installation of a 4-inch diameter monitoring well approximately 250 ft west/southwest of former monitoring well 18CPTMW22 for perchlorate delineation towards LHAAP-17 including completion of vertical soil profiling for perchlorate and VOCs in the Shallow Zone into the Wilcox clay.
- Installation of a 4-inch diameter monitoring well approximately 100 ft north of monitoring well 18CPTMW23 for perchlorate delineation towards Harrison Bayou including completion of vertical soil profiling for perchlorate and VOCs in the shallow zone formation into the Wilcox sand.

2.1.3 Wilcox Formation Groundwater Monitoring Wells

The scope of work in the Wilcox Formation groundwater included the following activities:

- Installation of a deep Wilcox 4-inch diameter monitoring well approximately 30 ft south of monitoring well 18CPTMW22SW including completion of vertical soil profiling for perchlorate and VOCs in the Wilcox Clay and Wilcox Formation.
- Installation of a 4-inch monitoring well adjacent to monitoring well 18CPTMW23 for lateral and vertical perchlorate and VOCs delineation in the Wilcox Formation including completion of vertical soil profiling for perchlorate and VOCs in the shallow zone formation and into the Wilcox Formation.

- Installation of an upper Wilcox 4-inch diameter monitoring well approximately 100 ft north of monitoring well 18CPTMW08SW and adjacent to 18CPTMW19 for vertical and lateral perchlorate and VOC delineation including completion of vertical soil profiling for perchlorate and VOCs in the Wilcox Formation.
- Installation of a 4-inch diameter monitoring well approximately 250 ft west/southwest of former monitoring well 18CPTMW22 for perchlorate delineation in the upper Wilcox Formation towards LHAAP-17 including completion of vertical soil profiling for perchlorate and VOCs (combined with the shallow zone formation profiling discussed above) into the upper Wilcox Formation.

Although the previous investigations identified data gaps in the soil and groundwater, this report discusses the data gaps identified in the soils. The groundwater data gaps, which included the installation of monitoring wells completed during this effort, will be addressed as part of the site semi-annual sampling program.

2.2 Summary of Site Investigation

The investigation activities completed to collect necessary data to address the identified data gaps are presented below.

The purpose of this investigation was to assess and potentially identify the source of perchlorate detected in the southern corner of the site and update the CSM in this area. The investigation involved the drilling and sampling of 17 soil boring locations using direct push technology (DPT) drilling techniques. The shallow subsurface field investigation was conducted between February 22 and March 15, 2016.

Additional investigation activities occurred between April 18 and June 27, 2016 involving the drilling and installation of 7 monitoring wells. Four of these monitoring wells (18CPTMW22R, 18CPTMW22DW, 18CPTMW26, and 18CPTMW26SW) were completed in the southern portion of the site to assist in the horizontal and vertical delineation of perchlorate in the subsurface. The other three monitoring wells were placed where data gaps were observed; 18CPTMW23SW, 18WW25, and 18CPTMW19SW were installed north-northwest of the site for lateral and vertical extent determination of perchlorate in groundwater.

Prior to conducting drilling and other subsurface activities during this investigation, the Texas One Call System was notified to locate underground utilities. The Texas One Call System was periodically updated during the course of the investigation.

2.2.1 Subsurface Soil Assessment

The Shallow Zone soils in the southern portion of the site were assessed by drilling and soil sampling using a DPT rig at the locations identified in the Supplemental PSI WP. The initial soil borings 18DPT01 through 18DPT05 were drilled, sampled, and analyzed for perchlorate and VOCs. Stepout soil borings in ordinate directions approximately 100 ft away from the impacted soil borings were completed in areas where contaminant of concern (COC) concentrations indicated the presence of contamination. Additional stepout soil borings were advanced and sampled until the concentrations of the COCs in soil were below soil GWP-Ind MSC or were below detection limits. The Shallow Zone soil borings terminated at the ñWilcox clay.ò During the course of this investigation, the Wilcox clay was interpreted to vary in depth from

approximately 11.5 to 36 ft bgs in the southern portion of the site. It was typically shallower in the soil borings located farther to the south. The proposed number of soil samples stated in the Supplemental PSI WP was five per borehole location; however due to the variations in borehole depths, the number of soil samples ranged between 4 soil samples and 7 soil samples. **Figure 2-1** presents the location of completed boreholes. The soil boring logs are provided in **Appendix A**.

Additional assessment in the southern portion of the site was accomplished by sampling the soil during the drilling and installation of monitoring wells 18CPTMW22R, 18CPTMW22DW, 18CPTMW26, and 18CPTMW26SW. Sonic drilling methods were used in the drilling and installation of these monitoring wells. 18CPTMW22R was drilled and completed as a replacement to plugged and abandoned monitoring well 18CPTMW22. Monitoring wells 18CPTMW26 and 18CPTMW26SW were drilled and sampled to delineate the COCs in the shallow and upper Wilcox zone, respectively to the west of LHAAP-18/24 towards LHAAP-17. Monitoring well 18CPTMW22DW was drilled to a depth of 90 ft bgs and used to vertically delineate the COCs in the lower Wilcox Formation. The borehole locations for these monitoring wells are presented in **Figure 2-1**.

A data gap existed with respect to the delineation of perchlorate and VOCs in the shallow zone, north of 18CPTMW23 near Harrison Bayou. To complete the vertical soil profile of perchlorate and VOCs in the shallow zone formation north of 18CPTMW23 towards Harrison Bayou, the borehole for monitoring well 18WW25 was drilled and sampled using a hollow stem auger drill rig near Harrison Bayou to a depth of 24 ft bgs. Soil samples were obtained at approximately 5-foot intervals. The Wilcox clay was not identified during drilling and sampling activities of this borehole. **Figure 2-2** provides the location of this well.

A data gap existed northwest of the site with respect to vertical delineation of perchlorate and VOC in the Wilcox Formation in proximity to monitoring well 18CPTMW23. Sonic drilling methods were used to drill and sample the soil boring and install monitoring well 18CPTMW23SW into the upper Wilcox Formation and complete the vertical soil profile for perchlorate and VOCs. Soil samples were obtained at approximately 10 ft intervals. The Wilcox clay was not identified during the drilling and sampling of the borehole. **Figure 2-2** provides the location of this well.

A data gap existed northwest of the site approximately 100 ft north of monitoring well 18CPTMW08SW adjacent to 18CPTMW19 in the Wilcox Formation. Sonic drilling methods were used to drill and sample the soil boring and install monitoring well 18CPTMW19SW into the upper Wilcox Formation and complete the vertical soil profile for perchlorate and VOCs. Soil samples were obtained at approximately 10 ft intervals. The Wilcox clay was identified at 20.3 ft bgs extending to a depth of 41.4 ft bgs. **Figure 2-2** provides the location of this well.

2.2.1.1 DPT

DPT drilling methods were used between February 22 and March 25, 2016 to drill 17 boreholes (18DPT01 through 18DPT17) located at the southern corner of the site to identify and delineate perchlorate in the Shallow Zone . The borehole locations are depicted in **Figure 2-1**.

Continuous soil samples were collected by pushing a 5-foot sample barrel at 5-foot increments. After the core barrel is advanced five ft (occasionally 2.5-ft increments were implemented due to flowing sands), the drill rods are removed from the borehole and the acetate sleeve containing the soil is removed from the sample barrel. Discrete soil samples were collected from each soil

boring location and analyzed for perchlorate and VOCs on an accelerated turnaround basis to allow rapid decisions on additional data collection. The discrete soil samples were collected at approximately 5-foot intervals, where significant photoionization detector (PID) readings were recorded, or at lithology changes. Samples were collected from the vadose zone, the saturated Shallow Zone, and in the Wilcox clay. In some instances where the Wilcox clay was not identified soil samples may have been obtained in the upper Wilcox sand. The general procedures used in DPT drilling are described in AECOM SOP 16 presented in the Final Installation-Wide Work Plan (AECOM, 2014).

A biased sampling approach was used to determine the source and extent of perchlorate in the Shallow Zone. Five borings were initially identified to start the investigation as shown in **Figure 2-1** by the orange-colored borehole symbols. Two initial DPT soil borings, one at the former Building 25-X (18DPT04) and one located midway between 18CPTMW22SW and 18DPT04 (18DPT05) were drilled and sampled to determine if building 25-X was contributing to the perchlorate in the subsurface. Since perchlorate was previously identified in 18CPTMW22SW, three initial DPT soil borings (18DPT01, 18DPT02, and 18DPT03) were drilled and sampled approximately 100 ft to the east, south, and west, respectively.

Based on the results of the five initial soil borings, additional soil borings at approximately 100 ft stepouts were advanced to the Wilcox Clay to delineate the perchlorate impact. The offset soil borings associated with each initial borehole are as follows:

- Initial boring 18DPT04; offset soil borings 18DPT06 (north), 18DPT07 (east), 18DPT15 (west), and 18DPT17 (south)
- Initial boring 18DPT05; offset soil boring 18DPT12 (southwest)
- Initial boring 18DPT01; offset soil borings 18DPT11 (north), 18DPT10 (east), and 18DPT14 (south)
- Initial borehole 18DPT02; offset soil borings 18DPT14 (east), 18DPT13 (south), 18DPT09 (west); and,
- Initial borehole 18DPT03; offset soil borings 18DPT09 (south), 18DPT08 (west), and 18DPT12 (north)

Per the direction of the USACE, soil borings 18DPT16, 18DPT15, and 18DPT17 were located in proximity to the former X-25 building location to determine if the former building is a source for perchlorate in the subsurface.

2.2.1.2 Sonic Drilling

Sonic drilling was primarily used to drill the boreholes beyond the reach of the DPT rig and for the installation of the monitoring wells. The well locations are depicted in **Figures 2-1 and 2-2**. Due to its versatility of using different diameter drill pipes, the sonic rig is able to install a temporary 8-inch surface casing in the shallow zone, to isolate the soil boring from the shallow zone while continuing to drill deeper into the subsurface. A 10-ft long 4-inch diameter core barrel was used to obtain the soil samples by advancing the core barrel into the subsurface by vibration which was followed with a 7-inch drill pipe to keep the hole from collapsing and isolating it from the surrounding lithology. Once the core barrel was advanced to a sufficient depth it was retrieved to the surface and the soil vibrated out into elongated plastic bags for

logging and sampling. When drilling below the Shallow Zone, a temporary 8-inch surface casing was installed into the clay to isolate the borehole from the Shallow Zone. Hydrated bentonite was used to seal the bottom of the temporary surface casing. The surface casing was then removed once the well was completed.

Further delineation south of the site was accomplished by sampling the soil during the drilling and installation of monitoring wells 18CPTMW22R, 18CPTMW22DW, 18CPTMW26, and 18CPTMW26SW. To address the other data gaps identified in the Final Updated PSI Report (AECOM, 2016), monitoring wells 18CPTMW19SW and 18CPTMW23SWwere drilled and sampled using a sonic drill rig; however, a hollow-stem auger (HSA) was used to drill Shallow Zone well 18WW25 as the area to the north of the site near Harrison Bayou was flooded and inaccessible at the time the sonic rig was available. Eight-and-a-quarter-inch diameter hollow stem augers were used to drill and install monitoring well 18WW25. A 5-foot long core barrel was used to continuously sample the borehole.

2.2.1.3 Subsurface Soil Samples

Seventy-eight discrete soil samples from 17 soil borings were collected for perchlorate and VOC analysis from the area on the south side of the site. During the investigation, the soil samples were obtained using DPT drilling techniques within the upper 45 ft of the subsurface (Shallow Zone groundwater). The soil samples were generally selected based on a combination of elevated PID results and soil type; however, soil samples were also selected where PID responses were low in various soil types to confirm non-detect/low concentrations of VOCs.

To augment the soil samples collected and analyzed during the DPT subsurface investigation, 23 discrete soil samples (12 shallow and 11 deep) were collected using the same criteria as the DPT investigation while drilling the soil borings for the monitoring wells. The soil samples from these soil borings further delineate the COCs horizontally as well as vertically (up to 90 ft bgs) in the southern portion of the site. Monitoring well 18CPTMW22R and 18CPTMW26 were drilled and installed in the Shallow Zone. 18CPTMW22R was drilled and installed as a replacement of plugged and abandoned well 18CPTMW22. Monitoring well 18CPTMW26SW was drilled and installed in the upper portion of the Wilcox sand; whereas 18SCPMW22DW was drilled and installed in the lower portion of the Wilcox sand. Eight-inch diameter temporary surface casing was used in both holes to isolate them from the Shallow Zone while drilling continued into the Wilcox sand.

North of the containment area soil borings for monitoring wells 18CPTMW19SW and 18CPTMW23SW were drilled and sampled to 64 ft bgs into the upper Wilcox Formation using sonic drilling techniques. A total of 14 soil samples, seven from 18CPTMW19SW and seven from 18CPTMW23SW were used to vertically profile the COCs in these soil borings. The soil boring for monitoring well 18WW25 was drilled and sampled within the shallow zone using a HSA drill rig. Five soil samples were obtained and analyzed to vertically profile the COCs within this soil boring. The methodology used to obtain subsurface soil samples followed the procedures described in AECOM SOP 05 presented in the Final Installation-Wide Work Plan (AECOM, 2014).

The soil samples were submitted to Microbac Laboratory, a Texas-licensed laboratory located in Marietta, Ohio for chemical analyses. The packaging and shipment of soil samples to the

laboratory followed the procedures described in AECOM SOP 08 presented in the Final Installation-Wide Work Plan (AECOM, 2014).

2.2.2 Groundwater Sampling

A comprehensive sampling event for groundwater was conducted in June 2016 after the monitoring wells were installed. A comprehensive groundwater gauging event was conducted on June 9, 2016 except for monitoring well 18WW25, which was not installed at the time the wells were gauged at the site on June 9, 2016. The gauging and sampling procedures followed the procedures described in the Installation-Wide Work Plan (AECOM, July 2014).

2.2.3 Field Quality Control Samples

2.2.3.1 Assessment of Field Procedures

As part of the Quality Control/Quality Assurance (QA/QC) procedures used during the field investigation, field quality control samples were obtained during sampling activities. The quality control samples included equipment blanks, trip blanks, and temperature blanks.

For each cooler containing samples for VOC analysis to be transported to the laboratory, a trip blank was included. The trip blank consisted of two laboratory-provided 40-milliliter VOA vials containing deionized water. This trip blank was used to determine whether the sample shipment may have been contaminated during transit from the field to the laboratory. The trip blanks were analyzed for VOCs.

A temperature blank was included in each cooler shipped to the laboratory. The temperature blank consists of a small laboratory-provided container containing water. It was used by the laboratory to confirm that the cooler arrived at the appropriate temperature.

2.2.3.2 Assessment of Field Variability

To evaluate or determine the source of measurement error arising from cumulative effects of both field and laboratory bias, duplicate samples were collected and submitted to the laboratory for analyses. One field duplicate was collected for approximately every 10 samples collected from each medium. The duplicate samples were analyzed for the same parameters as the media being sampled.

Laboratory control samples such as matrix spike (MS) and matrix spike duplicate (MSD) were collected during the sampling activities. These samples were evaluated by the laboratory to assess contamination introduced during sample preparation activities and/or from instrument contamination. One MS and MSD sample was collected approximately every 20 samples collected from each medium.

2.3 Surveying

The wells and boreholes were surveyed, and the results are presented in Exhibits 1 and 2.

2.4 Investigation Derived Waste

The investigation derived soil cuttings were placed in a roll-off box. The soil will be sampled, profiled and disposed in accordance with regulatory requirements. Water generated during drilling activities was added to the GWTP influent, treated, and disposed of accordingly. Other solid waste was disposed as municipal solid waste (i.e., trash).

2.5 Comparison of Planned and Actual Work Completed

There were no deviations from the Supplemental PSI WP.

Notes

1) All monitoring wells installed in 2013 have nomenclature beginning with "18CPT" with the exception of 18WW22 which was also installed in 2013.
2) "SW" at the end of well nomenclature indicates a shallow Wilcox Formation monitoring well (i.e., to a depth of 70 feet bgs).
3) "DW" at the end of well nomenclature indicates a deep Wilcox Formation monitoring well (i.e., to a depth of 100 feet bgs).
4) "P&A" - Plugged and Abandoned

3 INVESTIGATION FINDINGS

This section presents the data collected during this investigation in the context of addressing identified data gaps. This additional information is intended to improve the overall site conceptual model associated with hydrogeology, contaminant sources, and contaminant distribution in targeted areas of the site.

3.1 Hydrogeology

The subsurface investigation was conducted based on the LHAAP-18/24 Supplemental PSI WP (AECOM, 2015). Discrete soil samples were collected and tested for contaminant concentrations. Monitoring wells were installed in the shallow and Wilcox Formation to collect groundwater data.

3.1.1 Perchlorate Distribution in the Shallow Zone Soil at the Southern Area of Site

The soil data collected from DPT soil borings and the soil borings used to install the new groundwater monitoring wells for perchlorate, expanded the understanding of perchlorate presence and distribution within and outside the containment area in the Shallow Zone and Wilcox Formation. The location and concentration of perchlorate in these soil borings are depicted in **Figure 2-1**. The analytical results are presented in **Table 3-1**. **Table 3-1** also provides analytical results for VOCs. However, VOC concentrations were mostly nondetect with all concentrations reported above the detection limit below the MSC. **Table 3-1** also provides information about where the samples were collected from; the unsaturated Shallow Zone, saturated Shallow Zone, Wilcox clay, or Wilcox sand.

The perchlorate concentrations in the six DPT boreholes collected inside the containment area (18DPT04, 18DPT05, 18DPT06, 18DPT07, 18DPT16, and 18DPT17) in the southern portion of the site revealed perchlorate concentrations in the vadose zone were well below the MSC of 7,200 micrograms per kilogram (Õg/kg), with the highest concentration found in 18DPT04 at 5-5.5 ft bgs at 101 Õg/kg, followed by 18DPT16 at 5-5.5 ft bgs at 41.8 Õg/kg located adjacent to the former building X-25. These relatively low concentrations of perchlorate would indicate that perchlorate is not sourced from the surface release in this area or has since been flushed out of the shallow soil and no longer represent a source.

In the saturated zone within the containment area, the concentration of perchlorate was elevated particularly in the Wilcox clay, which is in direct contact with the base of the Shallow Zone soil. The highest concentration of perchlorate was detected in 18DPT04 at 36.5-37.0 ft bgs at 3,200 Õg/kg. This concentration is less than the GWP-Ind MSC of 7,200 Õg/kg. Therefore, there is no particular source of perchlorate identified in the Shallow Zone in this area of the site.

Outside the southern corner of the site, the concentration of perchlorate in the vadose zone ranged from a low 5.53 Õg/kg found in 18DPT12 at 5-5.5 ft bgs to nondetect found in all of the other soil borings. This lack of perchlorate in the vadose zone outside the containment indicates that perchlorate is not sourced from a surface release in this area.

Outside the southern corner in the shallow saturated zone, the concentrations of perchlorate were typically low, increasing in depth the closer the samples were to the Wilcox clay. The higher

concentrations of perchlorate in the shallow saturated zone were detected in 18DPT03 (3,290 Õg/kg at 14.5-15 ft bgs) , 18DPT15 (3,440 Õg/kg at 21-21.5 ft bgs), and 18DPT11 (3,940 Õg/kg at 20-20.5 ft bgs). These elevated concentrations of perchlorate were found in the coarser materials (sand) just above the Wilcox clay. The highest perchlorate concentrations in the Wilcox clay were detected in the borehole of monitoring well 18CPTMW22DW at 9,440 Õg/kg at 29.5-30 ft bgs and 18DPT12 at 15,900 Õg/kg at 18-18.5 ft bgs. These two results for perchlorate represent the only two soil samples exceeding the perchlorate MSC of 7,200 Õg/kg. The analytical results for the soil samples obtained from the boreholes of the monitoring wells are presented in **Table 3-2**. The elevated concentrations of perchlorate in 18DPT12 in the Wilcox clay may represent perchlorate that had migrated via groundwater to this location prior to installation of the groundwater extraction system.

The perchlorate concentrations for the stepout borings were considerably lower or nondetect. Therefore, the concentration of perchlorate in the Shallow Zone is considered delineated outside of the southern corner of the site to the southeast, south, and southwest. The results also support the absence of a perchlorate source in this area of the site. The soil boring data from the drilling and sampling of monitoring well 18CPTMW26 and boring 18DPT08 supported the delineation of perchlorate in the Shallow Zone to the southwest toward LHAAP-17.

The perchlorate concentration in the southern corner of the site is presented in **Figures 2-1.** A quality control summary and laboratory analytical reports (provided on compact disc) are presented in **Appendix B**.

3.1.2 Perchlorate Distribution in the Wilcox Formation Soil at Southern Area of Site

Soil samples from two borings drilled for the installation of Wilcox Zone monitoring wells (18CPTMW26SW and 18CPTMW22DW) were collected and analyzed to determine the extent of perchlorate in the Wilcox Formation. Additionally, due to the lack of Wilcox clay in boring 18DPT08, it would appear that soil samples obtained and analyzed at depth were from the Wilcox Formation.

The analytical results from 18CPTMW26SW and 18DPT08 reveal concentrations of perchlorate at low concentrations with the highest detected in 18DPT08 at 31.3 Õg/kg at a depth of 26-26.5 ft bgs. The highest concentration detected in 18CPTMW26SW was 4.6J Õg/kg at a depth of 20-20.5 ft bgs. The paucity of perchlorate concentrations in 18CPTMW26SW and 18DPT08 delineates the perchlorate in the Wilcox Zone to the southwest towards LHAAP-17.

The soil boring for 18CPTMW22DW was drilled and sampled to a depth of 90 ft bgs. The Wilcox clay appears to extend to a depth of 32.5 ft bgs, below which, sand with occasional thin clay layers are present. The highest concentration of perchlorate was detected in the Wilcox clay at 29.5-30 ft bgs at a concentration of 9,440 Õg/kg. Another soil sample obtained at 40-40.5 ft bgs in a small clay layer contained perchlorate at 4,040 Õg/kg. Perchlorate concentrations of samples obtained at depths of 50-51 ft revealed trace amounts of perchlorate (3.36J Õg/kg). Soil samples obtained at 60-60.5 ft, 70-70.5 ft, 80-80.5 ft and 89.5-90 ft bgs revealed no concentrations of perchlorate above the laboratory detection level, providing vertical extent determination of perchlorate in the Wilcox Formation. **Table 3-3** provides information about the monitoring wells. A quality control summary and laboratory analytical reports (provided on compact disc) are presented in **Appendix B**.

3.1.3 Perchlorate Data Gaps in the Soil Outside Containment Area to the Northwest

The soil boring locations for the monitoring wells as well as the concentration of perchlorate in the soils is presented in **Figure 2-2**. The boring logs are presented in **Appendix A**. The analytical results are summarized in **Table 3-2** and the analytical reports are presented in **Appendix B**. **Table 3-3** provides information about the monitoring wells.

Analytical results associated with locations near the southern corner are incorporated into the discussion in Section 3.1.2. Three monitoring well installations on the northwest side that included soil sampling and analysis are discussed below.

Monitoring Well 18CPTMW19SW

Saturated soil conditions were observed at approximately 10 ft bgs in the soil boring for monitoring well 18CPTMW19SW. This soil boring was drilled and sampled into the upper Wilcox Formation to a depth of 65 ft bgs. Perchlorate concentrations were below the detection limits in soil samples obtained at 5-5.5 ft bgs and 10-10.5 ft bgs. At 20-20.5 ft bgs perchlorate was present at 8.74 Õg/kg followed by no detection of perchlorate at 30-30.5 ft bgs. At 40-40.5 and 50-50.5 ft bgs perchlorate was detected at 124 Õg/kg and 170 Õg/kg, followed by no detections at 60-61 ft bgs (< 2.54 Õg/kg), providing vertical delineation of perchlorate at this location. The Wilcox clay appears to extend from 20.3 ft bgs to 41.4 ft bgs.

Monitoring Well 18CPTMW23SW

Saturated soil conditions were observed beginning at the surface in the soil boring for monitoring well 18CPTMW19SW as the area was subjected to flooding during this investigation associated with heavy rains. This soil boring was drilled and sampled into the upper Wilcox Formation to a depth of 65 ft bgs. Relatively low concentrations of perchlorate were detected in soil samples obtained at 5-5.5 ft bgs, 10-10.5 ft bgs and 20-20.5 ft bgs at 19.6 Õg/kg , 1,920 Õg/kg , and 29.3 Õg/kg, respectively. At depths of 30-30.4 ft bgs, 40-40.5 ft bgs, 50-50.5 ft bgs, and 60-60.5 ft bgs perchlorate concentrations were below the detection limits, providing vertical delineation of perchlorate at this location. The Wilcox clay was not identified in this soil boring.

Monitoring Well 18WW25

Soil was observed to be saturated at approximately 2 ft bgs within the soil boring for monitoring well 18WW25. Soil samples obtained and analyzed for perchlorate at 3.5-4 ft bgs 9.5-10 ft bgs, 14.5-15 ft bgs, 19.5-20 ft bgs, and 22-22.5 ft bgs were found to be below the laboratory detection limits, providing lateral delineation of perchlorate at this location. The Wilcox clay was not identified within the borehole at this location.

3.1.4 Soil VOC Results

The purpose of this work was mostly associated with perchlorate extent determination. However, VOC data was analyzed from the same soil samples collected for perchlorate analysis. The results indicated sporadic detection of VOCs with all concentrations below the VOC MSCs. **Tables 3-1 and 3-2** provide VOC results for the soil samples.

3.2 Groundwater Results

A comprehensive sampling event for groundwater was conducted in June 2016 after the monitoring wells were installed. A comprehensive groundwater level gauging event was conducted on June 9, 2016 except for well 18WW25, which was not installed until June 27, 2016, after the gauging event (well 18WW25 was however sampled on June 29, 2016 and analyzed for COCs). The results are described below.

3.2.1 Groundwater Elevation

Potentiometric surface maps for the Shallow Zone (**Figure 3-1**) and Wilcox Formation (**Figure 3-2**) were developed from monitoring well gauging data presented in **Table 3-4**. The Shallow Zone groundwater elevations indicate the presence of a localized groundwater high in the northern portion of the site, near monitoring wells AWD-1 and 123, similar to historical observations. The new monitoring well 18CPTMW22R, just outside the containment area to the south of the site, indicated the presence of a groundwater high. The groundwater elevation in 18CPTMW22R substantiates the historically high groundwater elevations observed in adjacent well MW-20, which represent the surface of a small perched groundwater. Therefore, the groundwater elevations in MW-20 and 18CPTMW22R were not used in contouring the Shallow Zone groundwater surface (Figure 3-1). New well 18CPTMW26 to the west of 18CPTMW22R had the lowest groundwater elevation in this area of the site at 167.08 ft above mean sea level (amsl).

The Wilcox Formation potentiometric results indicate the presence of a groundwater high in the vicinity of MW-14 in the northwest area of the site consistent with previous observations. New Wilcox Formation monitoring well 18CPTMW23SW north of MW-14 outside the containment has a groundwater elevation of 167.90 ft amsl, which is 5.76 lower than in MW-14 with a groundwater elevation of 173.66 ft amsl, indicating the presence of a horizontal gradient between MW-14 and 18CPTMW23SW. Groundwater elevation in new Wilcox Formation monitoring well 18CPTMW23SW is 2.18 ft lower than co-located monitoring Shallow Zone monitoring well 18CPTMW23, indicating the presence of a downward vertical gradient. A downward vertical gradient is also observed between Shallow Zone monitoring well 18CPTMW19 at an elevation of 171.70 ft amsl and new Wilcox Formation monitoring well 18CPTMW19SW at an elevation of 170.33 ft amsl.

To the south of the containment, new deep Wilcox Formation monitoring well 18CPTMW22DW has a groundwater elevation of 170.88 ft amsl, which is approximately 1 foot higher than the new upper Wilcox Formation monitoring well 18CPTMW22SW, indicating a slight upward gradient. The lateral gradient in the upper Wilcox Formation between new monitoring well 18CPTMW26SW and monitoring well 18CPTMW22SW appears to be to the east toward 18CPTMW22SW with an elevation difference between these wells of 0.42 ft. The vertical gradient appears to be upward between new upper Wilcox Formation monitoring well 18CPTMW26SW with a groundwater elevation of 170.29 ft amsl and new Shallow Zone monitoring well 18CPTMW26 with a groundwater elevation of 167.08 ft amsl.

3.2.2 Groundwater COC Concentrations

The June 2016 groundwater analytical results are presented in **Table 3-5**. A quality control summary and laboratory analytical reports (provided on compact disc) are presented in **Appendix B**. Groundwater sampling forms for June 2016 are presented in **Appendix C**.

3.2.2.1 Perchlorate

Figures 3-3 and 3-4 display the isoconcentration contours for perchlorate in the Shallow Zone and the Wilcox Formation, respectively. In the Shallow Zone, the highest concentrations of perchlorate occur in the vicinity of the UEP extending to the northeast outside the containment to 18WW17, which is bounded by non-detect results at wells 18CPTMW18 to the northeast and C-08 to the east. Monitoring well 18WW22, with a perchlorate concentration of 1.53 µg/L, defines the extent of this perchlorate hot spot to the north. Another area of high perchlorate extends from the ACD area to the south to include monitoring wells MW-7 and MW-23. The extent of perchlorate in the Shallow Zone groundwater is defined in all directions. To the south of the site outside the containment, new Shallow Zone monitoring well 18CPTMW22R had a low perchlorate concentration at 0.917 µg/L in contrast to the concentration in plugged monitoring well 18CPTMW22, which had a perchlorate concentration of 106,000 µg/L in June 2014. 18CPTMW22 was screened in the Wilcox clay between a depth of 19 and 28.5 ft bgs (see **Appendix A** for corrected 18CPTMW22 well log), where the highest concentrations of perchlorate occur, based on discrete soil sample data (see **Figure 2-2**). Wilcox clay in this area of the site occurs at a depth of approximately 12 feet bgs. New monitoring well 18CPTMW22R is screened between 4.8 ft and 14.3 ft bgs and partially penetrates Wilcox clay. Soil data from 18CPTMW22R indicates < 2.8 µg/kg of perchlorate in the soil to a depth of 15.5 ft bgs. The nondetect levels of perchlorate in the shallow soil reflect the very low concentration in 18CPTMW22 groundwater at 0.917 µg/L. In contrast, soil data from 18CPTMW22DW drilled in April 2016 indicates the presence of perchlorate at 5,400 µg/kg at a depth of 20 to 20.5 ft bgs. Soil samples collected from 18CPTMW22SW had perchlorate concentrations of 10,600 µg/kg at a depth of 24 ft bgs and 10,200 µg/kg at a depth of 26.5 ft bgs. These high concentrations of perchlorate in soil between 20 and 26.5 ft bgs coincide with the high perchlorate concentration reported in 18CPTMW22 screened across this soil interval.

New Shallow Zone monitoring well 18CPTMW26 located to the west of 18CPTMW22R between LHAAP-17 and LHAAP-18/24 had insufficient water to collect groundwater samples. New Shallow Zone monitoring well 18WW25 to the northwest adjacent to Harrison Bayou had a perchlorate concentration of < 0.20 µg/L, indicating that the perchlorate plume in this area of the site does not extend to Harrison Bayou.

In the Wilcox Formation, similar to previous results, the highest perchlorate concentrations were observed in the vicinity of 18CPTMW08SW (35,000 µg/L), near MW-5 to the north of the UEP, near the ACD in MW-14 (177,000 µg/L to 229,000 ug/L) northwest of the containment area, and to the south outside the containment in monitoring well 18CPTMW22SW (10,200 µg/L). All these wells are screened in the upper Wilcox Formation. New upper Wilcox Formation monitoring well 18CPTMW26SW, located to the west of 18CPTMW22SW (screen interval of 44.5 to 54.1 ft bgs) had a perchlorate concentration of 6.42 µg/L. This well defines the extent of perchlorate in the upper Wilcox Formation between sites LHAAP-17 and LHAAP-18/24. The perchlorate concentration in new deep Wilcox Formation monitoring well 18CPTMW22DW, screened between 72.7 to 82.3 ft bgs, was 1.21 J µg/L and defines the vertical extent of perchlorate at this location. New upper Wilcox Formation monitoring wells 18CPTMW19SW and 18CPTMW23SW in the northwest area had perchlorate concentrations of 1.25 µg/L and 0.407 µg/L, respectively. Along with wells 18WW19, 18WW09, and 18WW02, these wells provide lateral delineation of the extent of perchlorate in the upper Wilcox Formation. The extent

of perchlorate in the Wilcox Formation is defined in all directions. The extent of perchlorate is delineated vertically except at two locations in the Wilcox Formation at MW-14 and 18CPTMW08DW.

3.2.2.2 Trichloroethylene

Figures 3-5 and 3-6 display the isoconcentration contours for TCE in the Shallow Zone and the Wilcox Formation, respectively. In the Shallow Zone, the highest concentrations of TCE occur in the vicinity of the ACD in monitoring well 120 in the western area of the site, and in the area to the south of the UEP in monitoring well MW-2. TCE concentrations decrease with distance from MW-2 and 120, but remain above 1,000 µg/L in a large area of the site toward wells MW-21, 18CPTMW04, MW-23, MW-7, 129, MW-9, and AWD-1. The extent of TCE in the Shallow Zone is defined in all directions with the exception of TCE in MW-18 to the southwest of the site, which exceeded the Maximum Contaminant Level (MCL) of 5 µg/L with a concentration of 14.1 µg/L. To the south of the site outside the containment, new Shallow Zone monitoring well 18CPTMW22R had a TCE concentration < 0.2 µg/L in contrast to the concentration in plugged monitoring well 18CPTMW22, which had a TCE concentration of 58.9 µg/L in June 2014. 18CPTMW22 was screened in the Wilcox clay between a depth of 19 ft bgs and 28.5 feet bgs whereas new monitoring well 18CPTMW22R is screened to 14.3 ft bgs.

New Shallow Zone monitoring well 18CPTMW26, located to the west of 18CPTMW22R between LHAAP-17 and LHAAP-18/24, had insufficient water to collect a groundwater sample. New Shallow Zone monitoring well 18WW25 to the northwest adjacent to Harrison Bayou had a TCE concentration of < 0.5 µg/L, defining the extent of TCE in this area of the site and confirming that TCE from groundwater is not being released to Harrison Bayou.

In the Wilcox Formation, similar to previous results, the highest TCE concentrations were observed near the ACD in MW-14 (12,700 µg/L to 15,900 ug/L) northwest of the containment area, in the UEP area between 18CPTMW08SW (74.2 µg/L) and 18CPTMW01SW (46.5 µg/L), and in the central western portion of the site in 18CPTMW03SW. All these wells are screened in the upper Wilcox Formation. New upper Wilcox Formation monitoring well 18CPTMW26SW, located to the west of 18CPTMW22SW, had a TCE concentration of < 0.5 µg/L. This well defines the extent of TCE in the upper Wilcox Formation between sites LHAAP-17 and LHAAP-18/24. The TCE concentration in new deep Wilcox Formation monitoring well 18CPTMW22DW, screened between 72.7 to 82.3 ft bgs, was < 0.5 µg/L and defines the vertical extent of TCE at this location. New upper Wilcox Formation monitoring wells 18CPTMW19SW and 18CPTMW23SW in the northwest area had non-detectable TCE concentrations of < 0.5 µg/L. Along with wells 18WW19, 18WW09, and 18WW02, these wells define the lateral extent of TCE in the upper Wilcox Formation. The extent of TCE in the Wilcox Formation is defined in all directions.

3.2.2.3 Methylene Chloride

Figures 3-7 and 3-8 display the isoconcentration contours for MC in the Shallow Zone and the Wilcox Formation, respectively. In the Shallow Zone, the highest concentrations of MC occur in the vicinity of the ACD in monitoring well AWD-1 in the western area of the site, and in the area to the south of the UEP in monitoring well MW-2. MC concentrations decrease with distance from MW-2 and 120 to below detection levels in adjacent wells such as MW-21, MW-1,

18CPTMW04, MW-3, 109, MW-22, MW-9, and MW-12. The extent of MC in the Shallow Zone is defined in all directions. To the south of the site outside the containment, new Shallow Zone monitoring well 18CPTMW22R had an MC concentration < 0.2 μg/L, the same as the June 2014 concentration of MC in plugged monitoring well 18CPTMW22.

New Shallow Zone monitoring well 18CPTMW26, located to the west of 18CPTMW22R between LHAAP-17 and LHAAP-18/24, did not have sufficient water to collect a groundwater sample. New Shallow Zone monitoring well 18WW25, to the northwest adjacent to Harrison Bayou, had an MC concentration of < 0.5 μg/L, defining the lateral extent of MC in this area of the site and confirming that MC in Shallow Zone groundwater is not being released to Harrison Bayou.

In the Wilcox Formation, similar to previous results, the highest MC concentrations were observed near the ACD in MW-14 (53.5 J ug/L) northwest of the containment area, and to the south of the UEP area in 18CPTMW01SW (746 μg/L). These wells are screened in the upper Wilcox Formation. New upper Wilcox Formation monitoring well 18CPTMW26SW, located to the west of 18CPTMW22SW had an MC concentration of < 0.5 μg/L. This well defines the extent of MC in the upper Wilcox Formation between sites LHAAP-17 and LHAAP-18/24. The MC concentration in new deep Wilcox Formation monitoring well 18CPTMW22DW was < 0.5 μg/L and defines the vertical extent of MC at this location. New upper Wilcox Formation monitoring wells 18CPTMW19SW and 18CPTMW23SW in the northwest area had MC concentrations of < 0.5 μg/L. Along with wells 18WW19, 18WW09, and 18WW02, these wells define the lateral extent of MC in the upper Wilcox Formation. The extent of MC in the Wilcox Formation is defined in all directions.

3.2.2.4 1,4-Dioxane

Figures 3-9 and 3-10 display the isoconcentration contours for 1,4-dioxane in the Shallow Zone and the Wilcox Formation, respectively. In the Shallow Zone, the highest concentrations of 1,4-dioxane occur in the vicinity of the ACD in monitoring well 120 in the western area of the site, to the south of the ACD in monitoring well MW-7, and in the area to the south of the UEP in monitoring well MW-2. The maximum 1,4-dioxane concentration occurred in monitoring well 120 at a concentration 220 μg/L, and the second highest concentration was observed in MW-16 to the north of 120 toward Harrison Bayou at a concentration of 18 μg/L. MW-7 had a concentration of 13.4 μg/L, and 129 to the north of MW-7 had a 1,4-dioxane concentration of 6.52 μg/L. The 1,4-dioxane concentration in MW-2 was 7.58 μg/L. The extent of 1,4-dioxane in the Shallow Zone is defined in all directions, except for the area around MW-16, where the concentration of 1,4-dioxane exceeds the Texas Risk Reduction Program (TRRP) Tier 1 Groundwater Residential Protective Concentration Level (PCL) of 9.1 μg/L. To the south of the site outside the containment, new Shallow Zone monitoring well 18CPTMW22R had a 1,4-dioxane concentration < 1 μg/L.

New Shallow Zone monitoring well 18CPTMW26, located to the west of 18CPTMW22R between LHAAP-17 and LHAAP-18/24, did not have sufficient water to collect a groundwater sample. New Shallow Zone monitoring well 18WW25 to the northwest adjacent to Harrison Bayou had a 1,4-dioxane concentration of < 1 μg/L, defining the extent of 1,4-dioxane in this area of the site and confirming that 1,4-dioxane in Shallow Zone groundwater is not being released to Harrison Bayou at that location.

In the Wilcox Formation, similar to previous results, the highest 1,4-dioxane concentrations were observed near the ACD in MW-14 (390 to 412 ug/L) northwest of the containment area. MW-14 is screened in the upper Wilcox Formation. New upper Wilcox Formation monitoring well 18CPTMW26SW, located to the west of 18CPTMW22SW, had a 1,4-dioxane concentration of < 1 μg/L. This well defines the extent of 1,4-dioxane in the upper Wilcox Formation between sites LHAAP-17 and LHAAP-18/24. 1,4-Dioxane concentration in new deep Wilcox Formation monitoring well 18CPTMW22DW was < 1 μg/L, similar to the concentrations in co-located upper Wilcox Formation well 18CPTMW22SW. New upper Wilcox Formation monitoring wells 18CPTMW19SW and 18CPTMW23SW in the northwest area had 1,4-dioxane concentrations of < 1 μg/L. Along with wells 18WW09 and 18WW02, these wells define the lateral extent of 1,4-dioxane in the upper Wilcox Formation. The extent of 1,4-dioxane in the Wilcox Formation is defined in all directions.

3.2.2.5 Metals

Figures 3-11 and 3-12 display the metal exceedance concentrations in the Shallow Zone and the Wilcox Formation, respectively. In the Shallow Zone, the following metals were detected above the MCLs/PCLs in one or more monitoring wells: arsenic, barium, beryllium, cadmium, chromium, lead, manganese, and nickel. Fifteen monitoring wells were reported to have one or more metals above the MCLs/PCLs. The detections of metals above MCLs/PCLs in Shallow Zone groundwater is sporadic and does not suggest the presence of a source of metal COCs.

In the Wilcox Formation, three monitoring wells had metal concentrations above the MCL/PCL. Arsenic in 18CPTMW01SW and manganese in C-03 and 18WW18 were reported above the MCL/PCL.

3.3 Update to Cross-Section D-D’

An update to cross-section D-Dô that was originally presented in the *Final Updated Post-Screening Investigation Report for LHAAP-18/24, Burning Ground No. 3 and Unlined Evaporation Pond* (AECOM, 2016) is provided in **Appendix A**. The updated cross-section corrects the 18CPTMW22 well screen and adds information for boring/well logs 18CPTMW22SW and 18CPTMW22DW.

Notes

1) All monitoring wells installed in 2013 and 2014 have nomenclature beginning with "18CPT" with the exception of 18WW22 and 18WW24 which were also installed in 2013 and 2014, respectively.
2) "SW" at the end of well nomenclature indicates a shallow Wilcox Formation monitoring well (i.e., to a depth of 70 feet bgs).
3) "DW" at the end of well nomenclature indicates a deep Wilcox Formation monitoring well (i.e., to a depth of 100 feet bgs).
4) Only values exceeding the MCL or MSC have been included. MSC for Ni = 2.0 mg/L.

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analysis was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. 'UJ' not detects are not definite; the analyte may be present.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analysis was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. 'UJ' not detects are not definite; the analyte may be present.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analysis was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. 'UJ' not detects are not definite; the analyte may be present.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analysis was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. 'UJ' not detects are not definite; the analyte may be present.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analysis was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. 'UJ' not detects are not definite; the analyte may be present.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analysis was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. 'UJ' not detects are not definite; the analyte may be present.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analysis was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. 'UJ' not detects are not definite; the analyte may be present.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analysis was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. 'UJ' not detects are not definite; the analyte may be present.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/kg - micrograms per kilogram

Blue Highlighting Indicates concentrations above the MSC

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MSC - Medium-Specific Concentrations

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/kg - micrograms per kilogram

Table 3-3: LHAAP-18/24 Monitoring Well Specifications

Monitoring Well	Formation Designation	Well Diameter (Inches)	Ground Surface Elevation (ft amsl)	Top of Casing Elevation (feet amsl)	Delta TOC and Ground Surface	Borehole Depth	Casing Depth	Screened Interval	Surface Casing
						(In Feet from Ground Surface)			
18CPTMW19SW	Upper Wilcox	4	190.83	193.29	2.46	65.0	65.0	55.0-64.6	None
18CPTMW22R	Shallow Zone	4	185	187.23	2.23	16.0	14.4	4.4-14.0	None
18CPTMW22DW	Lower Wilcox	4	185.2	188	2.8	90.0	83.0	72.7-82.3	29.5
18CPTMW23SW	Upper Wilcox	4	174.77	177.43	2.66	65.7	65.7	55.3-65.0	30.0
18CPTMW26	Shallow Zone	4	180.06	182.8	2.74	15.0	14.7	4.7-14.3	None
18CPTMW26SW	Upper Wilcox	4	179.62	182	2.38	50.1	50.1	40.1-49.7	15.0
18WW25	Shallow Zone	4	172.34	175.15	2.81	24.2	24.2	14.2-23.8	None

amsl - above mean sea level

NS - not surveyed

TOC - top of casing

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

Location IDs containing "F" indicate sample filtered in the field with 10 micron filter.

Location IDs containing "FD" indicate duplicate samples.

Location IDs containing "B" indicate sample taken at bottom of screened interval and "T" indicate sample taken at top of screened interval.

Blue Highlighting Indicates Analyte Detected Above MCL/PCL

Note: Some samples may have been diluted due to the concentration(s) of one or more analytes exceeding the upper limit of the calibration curve.

J - Estimated: The analyte was positively identified, the quantitation is an estimation due to discrepancies in meeting certain analyte-specific quality control criteria.

MCL - Maximum Contaminant Level

mg/L - milligrams per liter

NA - not analyzed

PCL – Texas Residential Groundwater protective concentration level

U - Undetected: The analyte was analyzed for, but not detected.

UJ - The analyte was not detected; however, the result is estimated due to discrepancies in meeting certain analyte-specific quality control criteria.

ug/L - micrograms per liter

4 SUMMARY, CONCLUSIONS AND RECOMMENDATIONS

The information presented in this report was based on the LHAAP-18/24 Supplemental PSI WP (AECOM, 2015) that was reviewed by and concurrence was obtained from the TCEQ and the USEPA before implementation.

4.1 Summary

The following conclusions can be drawn from this investigation:

1. The information collected during this investigation achieved the objectives of the Supplemental PSI WP.
2. The lithology data collected in 2016 confirmed the updated CSM model and presence of Wilcox clay layer in the southern corner of the site, as well as northwest of the site in 18CPTMW19SW. The depth to the clay varied in the southern investigation area of the site from approximately 36 ft in the north (18DPT07) to 11.5 ft to the south (18DPT09). In the northwest area of the site in 18CPTMW23SW and 18WW25 in proximity to Harrison Bayou, the Wilcox clay layer was not encountered.
3. Discrete soil data in the southern portion of the site within the containment area revealed relatively low (101 Õg/kg in 18DPT04 at 5.5 ft bgs) to nondetectable concentrations of perchlorate in the vadose zone. In the shallow saturated zone, the highest concentration of perchlorate was detected in 18DPT04 at 36.5-37.0 ft bgs at 3,200 Õg/kg and below the MSC of 7,200 Õg/kg. Therefore, there is no particular source of perchlorate identified in the vadose or shallow saturated zone in the southern portion of the containment area.
4. Discrete soil data outside the southern portion of the containment area revealed relatively low (5.53 Õg/kg in 18DPT12 at 5-5.5 ft bgs) to nondetectable concentrations of perchlorate in the vadose zone. In the shallow saturated zone, the concentrations of perchlorate were typically low increasing in depth the closer the samples were to the Wilcox clay. The higher concentrations of perchlorate in the shallow saturated zone were detected in 18DPT03 (3,290 Õg/kg at 14.5-15 ft bgs), 18DPT15 (3,440 Õg/kg at 21-21.5 ft bgs), and 18DPT11 (3,940 Õg/kg at 20-20.5 ft bgs). These elevated concentrations of perchlorate were found in the coarser materials (sand) just above the Wilcox clay, but were below the MSC of 7,200 Õg/kg. Therefore, there is no particular source of perchlorate identified in the vadose or shallow saturated zone outside the southern portion of the containment area.
5. The highest perchlorate concentrations in the Wilcox clay were detected in the borehole of monitoring well 18CPTMW22DW at 9,440 Õg/kg at 29.5-30 ft bgs and 18DPT12 at 15,900 Õg/kg at 18-18.5 ft bgs (exceeding MSC of 7,200 Õg/kg). The elevated concentrations of perchlorate in 18DPT12 in the Wilcox clay may represent perchlorate that had migrated via groundwater to this location prior to installation of the groundwater extraction system.
6. Below the Wilcox clay and within the Wilcox sands in the southern portion of the site, the concentration of perchlorate generally decreases with the exception of 18DPT17 located within the containment area adjacent to the southwestern boundary.

7. Monitoring Well 18CPTMW19SW ï Low concentrations of perchlorate were reported in this boring with the highest concentration reported at 50-50.5 ft bgs at 170 Õg/kg in the Wilcox sand. The Wilcox clay appears to extend from 20.3 ft bgs to 41.4 ft bgs. The bottom soil sample at 60-61 ft bgs was < 2.54 Õg/kg for perchlorate providing vertical delineation.

8. Monitoring Well 18CPTMW23SW - relatively low concentrations of perchlorate were detected at 5-5.5 ft bgs, 10-10.5 ft bgs and 20-20.5 ft bgs at 19.6 Õg/kg , 1,920 Õg/kg, and 29.3 Õg/kg, respectively. At depths of 30-30.4 ft bgs, 40-40.5 ft bgs, 50-50.5 ft bgs, and 60-60.5 ft bgs perchlorate concentrations were below the detection limits, providing vertical delineation. Saturated conditions were observed at the surface and throughout the borehole as the area had previously been subjected to flooding due to heavy rains. Wilcox clay was not identified in this area of the site.

9. 18WW25 ï no perchlorate was detected in any of the analyzed soil samples at 3.5-4 ft bgs, 9.5-10 ft bgs, 14.5-15 ft bgs, 19.5-20 ft bgs, and 22-22.5 ft bgs. This well provides lateral extent delineation. Saturation at this location was encountered at approximately 2 ft bgs during drilling. The Wilcox clay was not identified.

10. VOC data was analyzed from the same soil samples collected for perchlorate analysis. The results indicated sporadic detection of VOCs with all concentrations below the VOC MSCs.

11. Groundwater elevation data in the Shallow Zone confirmed the presence of a groundwater high near AWD-2/123, similar to previous observations. Another groundwater high was identified to the south of the site in new Shallow Zone monitoring well 18CPTMW22R. This groundwater high substantiated the high historical groundwater elevations observed in adjacent well MW-20. The Wilcox Formation groundwater elevations indicate the presence of a groundwater high in the vicinity of MW-14 in the northwest area of the site, also consistent with previous observations.

12. New upper Wilcox Formation wells 18CPTMW19SW and 18CPTMW23SW and deep Wilcox Formation well 18CPTMW22DW provided additional vertical groundwater gradient information. Downward vertical gradients were observed between the Shallow Zone and upper Wilcox Formation in co-located wells 18CPTMW19/18CPTMW19SW and 18CPTMW23/18CPTMW23SW. However, an upward vertical gradient was observed between 18CPTMW22DW and new upper Wilcox Formation well 18CPTMW22SW.

13. Groundwater concentration data for perchlorate, TCE, MC, and 1,4-dioxane were collected and displayed as isoconcentration maps. The lateral extent of perchlorate, TCE, MC, and 1,4-dioxane in the Shallow Zone and in the Wilcox Formation has been determined with two exceptions. 1,4-Dioxane in MW-16 near Harrison Bayou had a concentration of 18 µg/L, exceeding the 1,4-dioxane PCL of 9.1 µg/L. The TCE result of 14.1 µg/L at MW-18, located to the southwest of the site, exceeded the MCL of 5 µg/L. New Shallow Zone monitoring well 18CPTMW26 located between LHAAP-18/24 and LHAAP-17 did not have sufficient water to collect a groundwater sample.

4.2 Conclusions

The following conclusions can be made based on the results of this investigation:

- No source of perchlorate was identified in the vadose zone soil or Shallow Zone groundwater outside or within the southern portion of the containment area.
- Perchlorate did not migrate to LHAAP-17 from LHAAP-18/24, based on low or non-detectable soil concentrations from 18CPTMW26, 18CPTMW26SW, and 18DP08.
- All VOC concentrations in soil were below the soil MSCs. Therefore, VOCs in the soil are not considered COCs in the southern area of the site.
- The Shallow Zone and Wilcox Formation wells define the lateral and vertical extent of perchlorate and VOCs above PCLs/MCLs in Shallow Zone and Wilcox Formation groundwater with the following exceptions: lateral extent of TCE in MW-18 in the Shallow Zone; vertical extent of perchlorate in the Wilcox Formation in MW-14 and 18CPTMW08DW.

4.3 Recommendations

The soil investigation results achieved the objectives of the work and no data gaps are identified. Accordingly, no further investigation of perchlorate concentrations in soil is recommended. The groundwater investigation results achieved the objectives of the work and provided lateral and vertical delineation of COCs in Shallow Zone and Wilcox Formation groundwater in the vicinity of the seven new wells. Groundwater samples will be collected from the site including monitoring well 18CPTMW26 during future semi-annual sampling events.

1 INTRODUCTION

AECOM reviewed 37 data packages from Microbac Laboratory Services, Marietta, OH. Groundwater and soil samples were collected February 24 through June 29, 2016 at LHAAP-18/24 at Longhorn Army Ammunition Plant (LHAAP), Karnack, Texas. Data were reviewed for conformance to the requirements of the following guidance documents: Automated Data Review by Laboratory Data Consultants (ADR.net), United States Environmental Protection Agency (EPA) Contract Laboratory Program National Functional Guidelines for Inorganic Data Review, (EPA, July 2002), and EPA Contract Laboratory Program National Functional Guidelines for Low Concentration Organic Data Review, (EPA, June 2001).

1.1 Intended Use of Data

The objective of this sampling event was to collect data to determine the extent of contaminants of concern at LHAAP-18/24.

Analyses requested included:

- SW6850 ï Perchlorates by LC/MS/MS
- SW8260- Volatiles by GC/MS
- SW6010 ï Al, Se, and Fe by ICP
- SW6020 ï As, Ba, Cd, Cr, Co, Pb, Mn, Ni, Ag, Se, V, Zn by ICP/MS
- 7470A- Hg by cold vapor atomic absorption
- SW8270- 1,4-dioxane by GC/MS

Table 2 lists the sample identifications and their associated laboratory identifications. **Table 3** lists qualified results with the associated quality control parameter that was exceeded.

1.2 Preservation and Holding Times

Sample identification data were evaluated for agreement with the chain-of-custody (COC). All samples were received in appropriate containers, within the proper temperature range, in good condition, and with the required signatures.

Sample L16061142-07 was analyzed 23 days after collection and therefore concentrations of all analytes are estimated (UJ/J).

Table 3 shows qualified analytical data.

1.3 Calibrations

Initial calibration criteria modification includes RSD< or = to 30%, two compounds allowed up to 40%. If the continuing calibration verification (CCV) compound exceeds 30% drift, the compound is checked in the LCS, if both are outside recovery limits, the compound is rejected, R. If only the CCV exceeds recovery criteria and is less than Ñ40% drift, then the compound is qualified J or UJ.

Table 3 shows qualified analytical data.

1.3.1 Continuing Calibration Verification (CCV)

1.3.1.1 SW8260

CCV WG572347-02 in SDG L16060411 has recoveries for bromomethane and naphthalene of 72% and 79.8%, respectively. These recoveries are below the 80% criteria for CCVs. The associated samples did not have reported concentrations of these analytes above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG572507-02 in SDG L16060504 has recoveries for acetone, 2-butanone, 1,2-dibromo-3-chloropropane, and 2-hexanone of 65.4%, 70.8%, 69.6%, and 75.4%, respectively. These recoveries are below the 80% criteria for CCVs. The associated samples did not have reported concentrations of these analytes above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG572735-02 in SDGs L16060615 and L16060616 has a recovery for bromomethane of 77.2%. This is below the 80% criteria for CCVs. The associated samples did not have reported concentrations of bromomethane above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG573037-02 in SDGs L16060616, L16060730, and L16060823 has a recovery for bromomethane of 74%. This is below the 80% criteria for CCVs. The associated samples did not have reported concentrations of bromomethane above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG573258-02 in SDG L16060650 has a recovery for 2-hexanone of 78.6%. This is below the 80% criteria for CCVs. The associated samples did not have reported concentrations of bromomethane above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG573770-02 in SDG L16060927 has a recovery for bromomethane of 73.4%. This is below the 80% criteria for CCVs. The associated samples did not have reported concentrations of bromomethane above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG573773-02 in SDG L16061026 has a recovery for 2-hexanone of 77.4%. This is below the 80% criteria for CCVs. The associated samples did not have reported concentrations of bromomethane above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG575085-02 in SDG L16061290 has recoveries for acetone, 2-butanone, 1,2-dibromo-3-chloropropane, 1,2-dichloroethane and 2-hexanone of 66.6%, 71.4%, 74.6%, 78.8% and 71.8%, respectively. These recoveries are below the 80% criteria for CCVs. The associated samples did not have reported concentrations of these analytes above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG575198-02 in SDGs L16061290, L16061452 and L16061453 has recoveries for acetone and 2-butanone of 78.8% and 79.4%, respectively. This is below the 80% criteria for CCVs. The associated samples did not have reported concentrations of bromomethane above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

CCV WG575663-02 in SDG L16061648 has a recovery for bromomethane of 79%. This is below the 80% criteria for CCVs. The associated samples did not have reported concentrations of bromomethane above the limit of detection (LOD) and therefore the concentrations are estimated (UJ).

Table 3 shows qualified analytical data.

1.4 Blanks

Where contamination by a target analyte of one of the various blanks was found, if the sample result for an associated sample was non-detect or less than 5X (10X for common laboratory contaminants) the analyte concentration in the blank, the corresponding sample result for the analyte was qualified B. Where the sample result for the affected analyte was greater than 5X the amount in the blank, no qualifier was applied.

All blanks are within criteria.

1.5 Surrogates

A recovery of 121% was reported for surrogate 1,2-dichloroethane-d4 in samples L16060730-03, L16060823-01, and L16060823-04 in SDGs L16060730 and L16060823. Recoveries are above the upper control limit of 120% and therefore reported concentrations for all analytes are estimated (UJ/J).

A recovery of 122% was reported for surrogate 1,2-dichloroethane-d4 in samples L16061142-02, L16061142-06 in SDGL16061142. Recoveries are above the upper control limit of 120% and therefore reported concentrations for all analytes are estimated (UJ/J).

A recovery of 123% was reported for surrogate 1,2-dichloroethane-d4 in sample L16061144-02 in SDG L16061144. Recoveries are above the upper control limit of 120% and therefore reported concentrations for all analytes are estimated (UJ/J).

Table 3 shows qualified analytical data.

1.6 Laboratory Control Sample (LCS)

The relative percent difference (RPD) for 1,4-dioxne between LCS WG573812-02 and LCSD WG573812-03 in SDGs L16061142 and L16061144 was 61.5% which is greater than the RPD limit of 30%. The associated samples reported concentrations below the LOD and therefore concentrations are estimated (UJ).

The percent recovery (%R) for 1,1-dichloroethene in LCS WG575129-02 was 69.5% in SDG L16061289. The lower control limit for 1,1-dichloroethene is 70% and the associated sample reported a concentration below the LOD, therefore the concentration is estimated (UJ).

The percent recoveries (%R) for 1,1-dichloroethene in LCS WG575199-02 and LCSD WG575199-03 were 54.9% and 54.7%, respectively, in SDGs L16061290, L16061452 and L1606143. The lower control limit for 1,1-dichloroethene is 70% and the associated samples reported concentrations below the LOD, therefore concentrations are estimated (UJ).

The percent recoveries (%R) for dichlorodifluoromethane in LCS WG575199-02 and LCSD WG575199-03 were 10.7% and 10.5%, respectively, in SDGs L16061290, L16061452 and

L1606143. The lower control limit for dichlorodifluoromethane is 30% and the associated samples reported concentrations below the LOD, therefore concentrations are estimated (UJ).

The percent recoveries (%R) for 2,2-dichloropropane in LCS WG575086-02 and LCSD WG575086-03 were 67.2% and 68.8%, respectively, in SDG L16061290. The lower control limit for 2,2-dichloropropane is 70% and the associated samples reported concentrations below the LOD, therefore concentrations are estimated (UJ).

The percent recoveries (%R) for chloromethane in LCS WG575199-02 and LCSD WG575199-03 were 31.1% and 30.9%, respectively, in SDGs L16061452 and L16061453. The lower control limit for chloromethane is 40% and the associated samples reported concentrations below the LOD, therefore concentrations are estimated (UJ).

The percent recoveries (%R) for vinyl chloride in LCS WG575199-02 and LCSD WG575199-03 were 31.1% and 30.9%, respectively, in SDGs L16061452 and L16061453. The lower control limit for vinyl chloride is 50% and the associated samples reported concentrations below the LOD, therefore concentrations are estimated (UJ).

Table 3 shows qualified analytical data.

1.7 Duplicates

Field duplicates were taken at a rate of 1 per every 20 samples. All duplicate recoveries were within the acceptable range of ≤30% for groundwater matrices and ≤50% for soil matrices.

1.7.1.1 Matrix Spike/Matrix Spike Duplicate (MS/MSD)

The MS/MSD for sample L16021306-02 in SDG L16021306 had RPDs that were outside of control limits for 1,1,2,2-tetrachloroethane, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-dibromo-3-chloropropane, 1,2-dichlorobenzene, 1,3-dichlorobenzene, 1,4-dichlorobenzene, 2-chlorotoluene and bromobenzene. L16021306-02 had concentrations of these analytes below the LOD and therefore the concentrations are estimated (UJ).

The MS/MSD for sample L16061068-13 in SDG L16061068 had RPDs that were outside of control limits for sodium, chromium, barium, and manganese and therefore reported concentrations are estimated (UJ/J).

Table 3 shows qualified analytical data.

2 DATA USABILITY SUMMARY

The data are usable for the intended purposes of the project. The data quality objectives have been met for the project.

Table 1: Completeness by Method

Method	No. of Rejected Results	% Completeness

Microbac

Laboratory Report Number: L16021240

Kayla Teague
AECOM Technical Services, Inc.
16000 Dallas Parkway
Dallas, TX 75248

Please find enclosed the analytical results for the samples you submitted to Microbac Laboratories. Review and compilation of your report was completed by Microbac's Ohio Valley Division (OVD). If you have any questions, comments, or require further assistance regarding this report, please contact your service representative listed below.

Laboratory Contact:
Stephanie Mossburg – Team Chemist/Data Specialist
(740) 373-4071
Stephanie.Mossburg@microbac.com

I certify that all test results meet all of the requirements of the DoD QSM and other applicable contract terms and conditions. Any exceptions are attached to this cover page or addressed in the method narratives presented in the report. All results for soil samples are reported on a 'dry-weight' basis unless specified otherwise. Analytical results for water and wastes are reported on a 'as received' basis unless specified otherwise. A statement of uncertainty for each analysis is available upon request. This laboratory report shall not be reproduced, except in full, without the written approval of Microbac Laboratories, DoD ELAP certification number 2936.01. The reported results are related only to the samples analyzed as received.

This report was certified on March 02 2016

David Vandenberg – Managing Director

State of Origin: TX

Record of Sample Receipt and Inspection

Comments/Discrepancies

This is the record of the shipment conditions and the inspection records for the samples received and reported as a sample delivery group (SDG). All of the samples were inspected and observed to conform to our receipt policies, except as noted below.

There were no discrepancies.

Discrepancy	Resolution

Coolers

Cooler #	Temperature Gun	Temperature	COC #	Airbill #	Temp Required?
00112730	I	0.0		J4599413984	X

Inspection Checklist

#	Question	Result
1	Were shipping coolers sealed?	Yes
2	Were custody seals intact?	Yes
3	Were cooler temperatures in range of 0-6?	Yes
4	Was ice present?	Yes
5	Were COC's received/information complete/signed and dated?	Yes
6	Were sample containers intact and match COC?	Yes
7	Were sample labels intact and match COC?	Yes
8	Were the correct containers and volumes received?	Yes
9	Were samples received within EPA hold times?	Yes
10	Were correct preservatives used? (water only)	NA
11	Were pH ranges acceptable? (voa's excluded)	NA
12	Were VOA samples free of headspace (less than 6mm)?	NA

Description	Yes	No	NA	NR	ER#
Chain-of-custody (C-O-C)					
Did samples meet the laboratory's standard conditions of sample acceptability upon receipt?	X				
Were all departures from standard conditions described in an exception report?	X				
Sample and quality control (QC) identification	X				
Are all field sample ID numbers cross-referenced to the laboratory ID numbers?	X				
Are all laboratory ID numbers cross-referenced to the corresponding QC data?	X				
Test reports					
Were all samples prepared and analyzed within holding times?	X				
Other than those results < MQL, were all other raw values bracketed by calibration standards?	X				
Were calculations checked by a peer or supervisor?	X				
Were all analyte identifications checked by a peer or supervisor?	X				
Were sample detection limits reported for all analytes not detected?	X				
Were all results for soil and sediment samples reported on a dry weight basis?	X				
Were % moisture (or solids) reported for all soil and sediment samples?	X				
Were bulk soils/solids samples for volatile analysis extracted with methanol per SW846 Method 5035?			X		
If required for the project, are TICs reported?			X		
Surrogate recovery data					
Were surrogates added prior to extraction?	X				
Were surrogate percent recoveries in all samples within the laboratory QC limits?	X				
Test reports/summary forms for blank samples	X				
Were appropriate type(s) of blanks analyzed?	X				
Were blanks analyzed at the appropriate frequency?	X				
Were method blanks taken through the entire analytical process, including preparation and, if applicable, cleanup procedures?	X				
Were blank concentrations < MQL?	X				
Laboratory control samples (LCS):					
Were all COCs included in the LCS?	X				
Was each LCS taken through the entire analytical procedure, including prep and cleanup steps?	X				
Were LCSs analyzed at the required frequency?	X				

Texas Risk Reduction Program (TRRP) Checklist

Laboratory Name:	Microbac OVD	**Laboratory Log Number:**	L16021240
Project Name:		**Method:**	8260

LRC Date:	2016-02-29 00:00:00		

Were LCS (and LCSD, if applicable) %Rs within the laboratory QC limits?		X			1
Does the detectability check sample data document the laboratory's capability to detect the COCs at the MDL used to calculate the SDLs?	X				
Was the LCSD RPD within QC limits?	X				
Matrix spike (MS) and matrix spike duplicate (MSD) data					
Were the project/method specified analytes included in the MS and MSD?			X		
Were MS/MSD analyzed at the appropriate frequency?			X		
Were MS (and MSD, if applicable) %Rs within the laboratory QC limits?			X		
Were MS/MSD RPDs within laboratory QC limits?			X		
Analytical duplicate data					
Were appropriate analytical duplicates analyzed for each matrix?			X		
Were analytical duplicates analyzed at the appropriate frequency?			X		
Were RPDs or relative standard deviations within the laboratory QC limits?			X		
Method quantitation limits (MQLs):					
Are the MQLs for each method analyte included in the laboratory data package?	X				
Do the MQLs correspond to the concentration of the lowest non-zero calibration standard?	X				
Are unadjusted MQLs and DCSs included in the laboratory data package?	X				
Other problems/anomalies					
Are all known problems/anomalies/special conditions noted in this LRC and ER?	X				
Was applicable and available technology used to lower the SDL to minimize the matrix interference effects on the sample results?	X				
Is the laboratory NELAC-accredited under the Texas Laboratory Accreditation Program for the analytes, matrices and methods associated with this laboratory data package?	X				
Initial calibration (ICAL)					
Were response factors and/or relative response factors for each analyte within QC limits?	X				
Were percent RSDs or correlation coefficient criteria met?	X				
Was the number of standards recommended in the method used for all analytes?	X				
Were all points generated between the lowest and highest standard used to calculate the curve?	X				
Are ICAL data available for all instruments used?	X				
Has the initial calibration curve been verified using an appropriate second source standard?	X

Initial and continuing calibration verification (ICCV and CCV) and continuing calibration blank (CCB):					
Was the CCV analyzed at the method-required frequency?	X				
Were percent differences for each analyte within the method-required QC limits?	X				
Was the ICAL curve verified for each analyte?		X			2
Was the absolute value of the analyte concentration in the inorganic CCB < MDL?			X		
Mass spectral tuning					
Was the appropriate compound for the method used for tuning?	X				
Were ion abundance data within the method-required QC limits?	X				
Internal standards (IS)					
Were IS area counts and retention times within the method-required QC limits?	X				
Raw data (NELAC Section 5.5.10)					
Were the raw data (for example, chromatograms, spectral data) reviewed by an analyst?	X				
Were data associated with manual integrations flagged on the raw data?	X				
Dual column confirmation					
Did dual column confirmation results meet the method-required QC?			X		
Tentatively identified compounds (TICs)					
If TICs were requested, were the mass spectra and TIC data subject to appropriate checks?			X		
Interference Check Sample (ICS) results					
Were percent recoveries within method QC limits?			X		
Serial dilutions, post digestion spikes, and method of standard additions					
Were percent differences, recoveries, and the linearity within the QC limits specified in the method?			X		
Method detection limit (MDL) studies					
Was a MDL study performed for each reported analyte?	X				
Is the MDL either adjusted or supported by the analysis of DCSs?	X				
Proficiency test reports					
Was the laboratory's performance acceptable on the applicable proficiency tests or evaluation studies?	X				
Standards documentation					
Are all standards used in the analyses NIST-traceable or obtained from other appropriate sources?	X

Compound/analyte identification procedures					
Are the procedures for compound/analyte identification documented?	X				
Demonstration of analyst competency (DOC)					
Was DOC conducted consistent with NELAC Chapter 5?	X				
Is documentation of the analyst's competency up-to-date and on file?	X				
Verification/validation documentation for methods (NELAC Chapter 5)					
Are all the methods used to generate the data documented, verified, and validated, where applicable?	X				
Laboratory standard operating procedures (SOPs)					
Are laboratory SOPs current and on file for each method performed	X				

1. Items identified by the letter “R” must be included in the laboratory data package submitted in the TRRP-required report(s). Items identified by the letter “S” should be retained and made available upon request for the appropriate retention period;

2. O = organic analyses; I = inorganic analyses (and general chemistry, when applicable);

3. NA = Not applicable;

4. NR = Not reviewed;

5. ER# = Exception Report identification number (an Exception Report should be completed for an item if “NR” or “No” is checked).

The Exception Report for each “No” or “Not Reviewed (NR)” item in Laboratory Review Checklist and for each analyte, matrix, and method for which the laboratory does not hold NELAC accreditation under the Texas Laboratory Accreditation Program.

Release Statement: I am responsible for the release of this laboratory data package. This laboratory is NELAC accredited under the Texas Laboratory Accreditation Program for all the methods, analytes, and matrices reported in this data package except as noted in the Exception Reports. The data have been reviewed and are technically compliant with the requirements of the methods used, except where noted by the laboratory in the Exception Reports. By my signature below, I affirm to the best of my knowledge all problems/anomalies observed by the laboratory have been identified in the Laboratory Review Checklist, and no information affecting the quality of the data has been knowingly withheld.

Check, if applicable: [ ] This laboratory meets an exception under 30 TAC §25.6 and was last inspection by [ ] TCEQ or [ ] _____ on **(enter date of last inspection**). Any findings affecting the data in this laboratory data package are noted in the Exception Reports herein. The official signing the cover page of the report in which these data are used is responsible for releasing this data package and is by signature affirming the above release statement is true.

Exceptions Report

1)Dichlorodifluoromethane and Vinyl chloride exceeded the UCL in the LCS/LCS2 analyzed 02/26/16 on HPMS9. Dichlorodifluoromethane exceeded the UCL in the LCS analyzed 02/28/16 on HPMS9.
2)Dichlorodifluoromethane exceeded the UCL in ICV analyzed 02/25/16 on HPMS9.

Were data associated with manual integrations flagged on the raw data?			X		
Dual column confirmation					
Did dual column confirmation results meet the method-required QC?			X		
Tentatively identified compounds (TICs)			X		
If TICs were requested, were the mass spectra and TIC data subject to appropriate checks?			X		
Interference Check Sample (ICS) results					
Were percent recoveries within method QC limits?			X		
Serial dilutions, post digestion spikes, and method of standard additions			X		
Were percent differences, recoveries, and the linearity within the QC limits specified in the method?			X		
Method detection limit (MDL) studies					

Microbac

Texas Risk Reduction Program (TRRP) Checklist

Laboratory Name:	Microbac OVD	**Laboratory Log Number:**	L16021240
Project Name:		**Method:**	PCT-S
Prep Batch Number(s):	WG558757	**Reviewer Name:**	Deanna Hesson
LRC Date:	2016-02-26 00:00:00		

Was a MDL study performed for each reported analyte?			X		
Is the MDL either adjusted or supported by the analysis of DCSs?			X		
Proficiency test reports					
Was the laboratory's performance acceptable on the applicable proficiency tests or evaluation studies?	X				
Standards documentation					
Are all standards used in the analyses NIST-traceable or obtained from other appropriate sources?			X		
Compound/analyte identification procedures					
Are the procedures for compound/analyte identification documented?	X				
Demonstration of analyst competency (DOC)					
Was DOC conducted consistent with NELAC Chapter 5?	X				
Is documentation of the analyst's competency up-to-date and on file?	X				
Verification/validation documentation for methods (NELAC Chapter 5)	X				
Are all the methods used to generate the data documented, verified, and validated, where applicable?	X				
Laboratory standard operating procedures (SOPs)					
Are laboratory SOPs current and on file for each method performed	X				

1. Items identified by the letter “R” must be included in the laboratory data package submitted in the TRRP-required report(s). Items identified by the letter “S” should be retained and made available upon request for the appropriate retention period;
2. O = organic analyses; I = inorganic analyses (and general chemistry, when applicable);
3. NA = Not applicable;
4. NR = Not reviewed;
5. ER# = Exception Report identification number (an Exception Report should be completed for an item if “NR” or “No” is checked).

The Exception Report for each “No” or “Not Reviewed (NR)” item in Laboratory Review Checklist and for each analyte, matrix, and method for which the laboratory does not hold NELAC accreditation under the Texas Laboratory Accreditation Program.

Release Statement: I am responsible for the release of this laboratory data package. This laboratory is NELAC accredited under the Texas Laboratory Accreditation Program for all the methods, analytes, and matrices reported in this data package except as noted in the Exception Reports. The data have been reviewed and are technically compliant with

Texas Risk Reduction Program (TRRP) Checklist

Laboratory Name:	Microbac OVD	**Laboratory Log Number:**	L16021240

the requirements of the methods used, except where noted by the laboratory in the Exception Reports. By my signature below, I affirm to the best of my knowledge all problems/anomalies observed by the laboratory have been identified in the Laboratory Review Checklist, and no information affecting the quality of the data has been knowingly withheld.

Check, if applicable: [ ] This laboratory meets an exception under 30 TAC §25.6 and was last inspection by [ ] TCEQ or [ ] _____ on **(enter date of last inspection**). Any findings affecting the data in this laboratory data package are noted in the Exception Reports herein. The official signing the cover page of the report in which these data are used is responsible for releasing this data package and is by signature affirming the above release statement is true.

2.1.1.2 QC Summary Data

Example 8260 Calculations

1.0 Calculating the Response Factor (RF) from the initial calibration (ICAL) data:

RF = [(Ax) (Cis)] / [(Ais) (Cx)]

where:	Example
Ax = Area of the characteristic ion for the compound being measured:	3399156
Cis = Concentration of the specific internal standard (ug/mL)	25
Ais = Area of the characteristic ion of the specific internal standard	846471
Cx = Concentration of the compound in the standard being measured (ug/mL)	100
RF = Calculated Response Factor	**1.0039**

2.0 Calculating the concentration (C) of a compound in water using the average RF: *

Cx = [(Ax) (Cis) (Vn)(D)] / [(Ais) (RF) (Vs)]

where:	**Example**
Ax = Area of the characteristic ion for the compound being measured	**3122498**
Cis = Concentration of the specific internal standard (ug/L)	**25**
D = Dilution factor for sample as a multiplier (10x = 10)	**1**
Ais = Area of the characteristic ion of the specific internal standard	**611048**
RF = Average RF from the ICAL	**1.004**
Vs = Purge volume of sample (mL)	**10**
Vn = Nominal purge volume of sample (mL) (10.0 mL)	**10**
Cx = Concentration of the compound in the sample being measured (ug/L)	**127.2428**

3.0 Calculating the concentration (C) of a compound in soil using the average RF: *

Cx = [(Ax) (Cis) (Wn)(D)] / [(Ais) (RF) (Ws)]

where:	**Example**
Ax = Area of the characteristic ion for the compound being measured	**3122498**
Cis = Concentration of the specific internal standard (ug/L)	**25**
D = Dilution factor for sample as a multiplier (10x = 10)	**1**
Ais = Area of the characteristic ion of the specific internal standard	**611048**
RF = Average RF from the ICAL	**1.004**
Ws = Weight of sample purged (g)	**5**
Wn = Nominal purge weight (g) (5.0 g)	**5**
Cx = Concentration of the compound in the sample being measured (ug/L)	**127.2428**

Dry weight correction:

Percent solids (PCT_S)	**50**
Cd = (Cx) (100)/PCT_S	**254.4856**

* Concentrations appearing on the instrument quantitation reports are on-column results and do not take into account initial volume, final volume, and the dilution factor.

4.0 Concentration from Linear Regression

Step 1: Retrieve Curve Data From Plot, y = mx + b

y = response ratio = response of analyte / response of IS = Ax/Ais

x = amount ratio = concentration analyte/concentration internal standard = Cx / Cis

m = slope from curve = 0.213

b = intercept from curve = - 0.00642

Step 2: Calculate y from Quantitation Report

y = 86550/593147 = 0.1459

Step 3: Solve for x

x = (y - b)/m = [(0.1459 -(- 0.00642)]/ 0.213 = 0.7152

Step 4: Solve for analyte concentration Cx

Cx = Cis (x) = (25.0)(0.7152) = 17.88

Example Spreadsheet Calculation:

Slope from curve, m:	**0.213**
Intercept from curve, b:	**-0.00642**
Area of analyte, Ax:	**86550**
Area of Internal Standard , Ais:	**593147**
Concentration of IS, Cis	**25.00**
Response Ratio:	**0.145917**
Amount Ratio:	**0.715195**
Concentration:	**17.87988**
Units of Internal Standard:	**ug/L**

5.0 Concentration from Quadratic Regression

Step 1 - Retrieve Curve Data from Plot, y = Ax^2 + Bx + C
Where:
Ax^2 + Bx + (C - y) = 0
A, B, C = constants from the ICAL quadratic regression
y = Response ratio = Area of analyte/Area of internal standard (IS)
x = Amount ratio = Concentration of analyte/concentration of IS

Step 2: Calculate y from Quantitation Report

y = Ax/Ais

Step 3: Solve for x using the quadratic formula
Ax^2 + Bx + C - y = 0

$$x = \frac{b \pm \sqrt{\left(b^2 - 4a(c - y)\right)}}{2a}$$ (Two possible solutions)

Step 4: Solve for analyte concentration Cx

Cx = (Cis)(Amount ratio)

Example Spreadsheet Calculation:

Value of A from plot:	**-0.00629**	
Value of B from plot:	**0.511**	
Value of C from plot:	**-0.0276**	
Area of unknown from quantitation report:	**293821**	
Area of IS from quantiation report:	**784848**	
Response ratio, y:	**0.374367**	
C - y:	**-0.40197**	
Root 1 - Computed amount ratio , X1:	**80.44567**	
Root 2 - Computed amount ratio , X2:	**0.794396**	use this solution
Concentration of IS, Cis:	**25.00**	
Concentration of analyte, Cx:	**19.86**	ug/L
