LONGHORN ARMY AMMUNITION PLANT KARNACK, TEXAS

ADMINISTRATIVE RECORD

CHRONOLOGICAL INDEX

Volume 21 of 25

2007

Bate Stamp Numbers
00059206 - 00060025

Prepared for

Department of the Army
Longhorn Army Ammunition Plant

1976 – 2007

LONGHORN ARMY AMMUNITION PLANT
KARNACK, TEXAS
ADMINISTRATIVE RECORD – CHRONOLOGICAL INDEX

VOLUME 21 of 25

2007

A. Title: Report (continued) – Final Installation-Wide Baseline Ecological Risk Assessment
Volume I: Step 3 Report - Exhibit 1 – Data Report
Author(s): Shaw
Recipient: All Stakeholders
Date: November 15, 2007
Bate Stamp: 00059206 - 00059407

B. Title: Report (continued) – Final Installation-Wide Baseline Ecological Risk Assessment
Volume II: Steps 4 through 8 Report and Appendices L through P
Author(s): Shaw
Recipient: All Stakeholders
Date: November 15, 2007
Bate Stamp: 00059408 - 00060025

00059206

Foreword

The objective of the Installation-Wide Baseline Ecological Risk Assessment is to present the detailed results of the U.S. Environmental Protection Agency's eight-step ecological risk assessment process as it is applied at the Longhorn Army Ammunition Plant (LHAAP). Volume I: Step 3 Report described the problem formulation and technical approach implemented at LHAAP including the selection of final constituents of potential ecological concern. Additional information regarding the further consideration of these final constituents of potential ecological concern is discussed in depth in Volume II: Steps 4 through 8, using site-specific data collected at the Installation as part of the eight-step ecological risk assessment process. A discussion of Steps 4 through 8, including Step 4: Study Design and Data Quality Objectives, Step 5: Verification of Field Sampling Design, Step 6: Site Investigation and Data Analysis that includes a description of collection techniques, Step 7: Risk Characterization, and Step 8: Risk Management, is presented herein.

12.0 Step 4: Study Design and Data Quality Objectives Process

Section 12.0 presents a summary of the Step 4 Study Design and Data Quality Objectives Process. Much of this information is also presented in the *Final Baseline Ecological Risk Assessment Field Sampling Work Plan* (Shaw, 2006b).

Step 4 of the ERA process represents the identification and design of the scientifically defensible site-specific investigations necessary to address the risk questions previously developed (**Section 11.0**). Specifically, Step 4 includes the following:

- Identification of specific data needs
- A restatement of the selection of assessment endpoints and specific measurement endpoints
- Determination of the type and amount of necessary data
- Identification of the specific methods for collecting and analyzing the data
- Selection of the appropriate risk characterization approach
- Selection of the specific study methods (e.g., toxicity tests, field surveys, tissue analyses)

12.1 Establishing Measurement Endpoints

A measurement endpoint represents that characteristic of the assessment endpoint that is directly measured in the BERA and used to establish, if possible, cause-and-effect relationships between the COPECs and the assessment endpoint. As presented in **Tables 12-1** and **12-2**, multiple measurement endpoints were evaluated for each assessment endpoint to support estimates of hazard associated with final COPECs in the soil and sediment at LHAAP. As discussed in **Volume I** (**Section 5.0**), all of the assessment endpoints listed relate to protection of populations and/or communities at LHAAP. It should be noted that some measurement endpoints are included in **Tables 12-1** and **12-2** that were not selected for further field work in the BERA. Specifically, assessment endpoint 3 (AE-3) in **Table 12-1**, which lists the protection of terrestrial plant and invertebrate populations as an assessment endpoint, was not further refined through additional field work in the BERA. This assessment endpoint was included as part of a project-specific agreement with LHAAP stakeholders in which organisms at the base-of-the-food-chain (i.e., plants and terrestrial invertebrates) would be evaluated as assessment endpoints, but remediation decisions would not be made based on the results of this evaluation. This compares with AE-1 (survival, growth, or reproduction of aquatic biota living in sediment), for which additional BERA field work was completed. Although aquatic biota living in sediment are base-

of-the-food-chain receptors as well, these receptors are formally evaluated as assessment endpoints due to the fact that USEPA and Texas promulgated ambient water quality criteria exist for the protection of aquatic life. No similar promulgated criteria exist for the protection of terrestrial base-of-the-food-chain receptors.

Measurement endpoints for the BERA include measures for both exposure (i.e., bioaccumulation) and effects (i.e., aquatic invertebrate mortality and growth). Measures for sediment toxicity effects and bioaccumulation and incidental soil and sediment ingestion exposures are addressed in the following subsections. The measurement endpoints are correlated with testable hypotheses, which are detailed in **Table 12-2**. It should be noted that Assessment Endpoint No. 3 (Protection of terrestrial plant and invertebrate populations) does not have a Step 4 measurement endpoint, risk question, or testable hypothesis, as it has been agreed to by all parties that no soil cleanup is necessary for the protection of base-of-the-food-chain receptors.

Site-specific data have been collected to support the analysis of some of the measurement endpoints. Details are presented in **Section 14.0**. Discussions on the use of the data collected are presented after the discussion of the measurement endpoints. Additional information regarding the use of the data is provided in the detailed presentation of the risk questions (**Section 12.3**, Data Quality Objectives and Statistical Considerations).

12.1.1 Sediment Toxicity

Laboratory toxicity tests measure toxicological effects of bioavailable fractions of COPECs in sediment under controlled conditions. Under Assessment Endpoint No. 1 these tests provide a relatively rapid, integrated measure of the effects of the COPECs in the sediment sample on a toxicologically sensitive form of test organism deemed appropriate for the environmental medium being evaluated. Laboratory measurements for sediment toxicity provide a number of advantages that include the following:

- Results integrate the additive and interactive effects of complex mixtures of COPECs that may be present in sediment
- Depending on the selected test, various endpoints may be examined using different exposure periods to predict potential impact at several levels of biological organization including physiological (e.g., growth), ontogenetic (development), behavioral (burrowing), or population (reproduction and mortality)
- Measures of toxicological effects can be incorporated into a subsequent remediation strategy either directly as a test of toxicity of field-collected sediment or indirectly as a component in the development of site-specific sediment quality criteria

The measurement endpoints recommended and used for the assessment of sediment toxicity are summarized in **Table 12-2** and include the following:

- Laboratory survival, growth, or reproduction of sediment-dwelling invertebrates
- The use of Acid Volatile Sulfides – Simultaneously Extracted Metals (AVS-SEM) data from the site to assess bioavailability

Results of toxicity tests are used to determine whether mean survival, growth, or reproduction of test organisms exposed to site media differs from survival, growth, or reproduction measured for test organisms exposed to control media and reference location areas. Details on the quantity and locations of samples were presented in the Sampling and Analysis Plan (SAP) (Shaw, 2006b).

12.1.2 Bioaccumulation Exposures

Details of the approaches for the assessment of exposures for bioaccumulation of COPECs for food-chain pathways for receptors selected to represent assessment endpoints are provided in **Tables 12-1** and **12-2**. Receptor bioaccumulation exposures for Assessment Endpoint No. 2 (i.e., assessment endpoints for birds and mammals) are assessed as either field-collected or laboratory-measured whole-organism tissue concentrations for a COPEC. The measurement endpoints associated with bioaccumulation exposure that have been identified for Assessment Endpoint No. 2 include the following:

Assessment Endpoint No. 2: Survival, growth, and reproduction of birds and mammals

- Sediment invertebrate bioaccumulation is estimated using laboratory bioaccumulation studies (freshwater aquatic worms)
- Plant bioaccumulation is estimated using co-located soil and plant samples
- Soil invertebrate bioaccumulation is estimated using laboratory bioaccumulation studies (earthworms)

Analytical data collected for estimating or measuring bioaccumulation for each measurement endpoint listed in **Table 12-2** is combined to calculate tissue concentrations for assessing potential hazard to birds and mammals that ingest plants and/or terrestrial or benthic invertebrates. For example, site-specific BAFs are multiplied by 95 percent UCL soil or sediment COPEC concentrations to estimate tissue concentrations (**Section 14.2**). Details for the quantity and locations of the samples that were used to calculate these BAFs were presented in the SAP (Shaw, 2006b**)**.

12.2 Study Design

The primary objective of the study design is to guide the preparation of a work plan and SAP that identifies the scientifically defensible investigations that will be used to evaluate the exposure and effects of COPECs at LHAAP based on the assessment endpoints initially identified in

Section 3.0 and refined in (**Volume I**) **Section 11.2** and in **Section 12.1**. These investigation methods are designed to address the following:

- Identify cause-and-effect relationships between COPECs and assessment endpoints
- Support a defensible risk characterization
- Support a risk management decision
- Support the development of EcoPRGs (if necessary)

Activities for the study design include refining measurement endpoints, if needed, for each assessment endpoint and developing assessment endpoint-specific methods using the DQO process.

12.3 Data Quality Objectives and Statistical Considerations

The DQO process is used to develop data to support defensible risk management decisions for the BERA. Information is incorporated during the DQO process to focus the study design. Output from the DQO process clarifies the objectives of sample collection and determines where and when to collect samples, limitations on sample collection, and the level of uncertainty that may be acceptable.

A critical component of the DQO process is the development of decision rules for the risk questions that have been developed. Guidance from the U.S. Department of the Navy (2001) states:

> "The output of the first four steps of the DQO process are integrated into a statement, the decision rule, which describes that logical basis for making a decision. A decision rule is an 'if…, then…' statement that defines the conditions that would cause the decision-maker to choose an action. In other words, it establishes the exact criteria for making a choice between taking or not taking an action."

The decision rule includes the following three main elements:

- The parameter of interest (e.g., protection of birds from sediment-based COPECs)
- An action level (specific to the measurement endpoint selected)
- Alternative actions or decision choices

12.3.1 Decision Rules for Risk Questions to Assessment Endpoint No. 1

Two measurement endpoints have been selected to assess the effects of sediment-derived COPECs on the survival, growth, or reproduction of aquatic biota in the aquatic environments of LHAAP, as presented in **Table 12-2**. For the relevant measurement endpoints, a statistically significant reduction of survival, growth, or reproduction by 20 percent or more (compared with the reference location or laboratory control if a reference is not available) is deemed potentially

biologically relevant. Each measurement endpoint has an associated risk question and a testable hypothesis from which specific decision rules can be derived, as follows.

Risk Question 1-1: Does exposure to site sediment cause reduced survival, growth, or reproduction for invertebrates in sediment?

> **Testable Hypothesis 1-1**: Means of laboratory survival, growth, or reproduction for invertebrates in site and reference location sediment and control are not significantly different.
>
> Decision Rule 1: If Testable Hypothesis 1-1 is accepted, a COPEC in site sediment poses an acceptable low hazard for invertebrates, as study results indicate that the mean survival, growth, or reproduction rates of invertebrates are not significantly impacted by COPECs in site sediment, relative to COPECs in sediment from an upgradient reference location or laboratory control.
>
> Decision Rule 2: If Testable Hypothesis 1-1 is rejected (and laboratory survival, growth, or reproduction is statistically lower than the reference location and the laboratory control), a COPEC in site sediment may pose an unacceptable hazard for invertebrates, as study results indicate that the mean survival, growth, or reproduction rates of invertebrates are impacted by COPECs in site sediment, relative to COPECs in sediment from an upgradient or other appropriate reference location and the laboratory control.

It should be noted that details on the acceptability criteria for the laboratory control and biologically significant differences were discussed in **Appendix A**, Section 5.2, of Shaw (2006b). If Decision Rule 2 is supported by the data and a clear dose-response relationship is observed, action levels of COPECs in sediment may be recommended.

Risk Question 1-2: Are metal COPECs bioavailable such that exposure to site sediment causes reduced survival, growth, or reproduction for invertebrates in sediment?

> **Testable Hypothesis 1-2**: Most (e.g., > 50 percent) of the AVS-SEM ratios in the samples are greater than 1, suggesting low bioavailability of metals.
>
> Decision Rule 1: If Testable Hypothesis 1-2 is accepted, a COPEC in sediment poses an acceptable low hazard for aquatic biota, as the findings indicate that survival, growth, and reproduction are not adversely impacted by COPECs in sediment because they are not bioavailable.
>
> Decision Rule 2: If Testable Hypothesis 1-2 is rejected, a COPEC in sediment may pose an unacceptable hazard for aquatic biota, as the findings indicate that survival, growth, or

reproduction may be adversely impacted by COPECs in sediment because they are bioavailable.

It should be noted that AVS-SEM results are used as a second line of evidence for describing sediment toxicity or the lack thereof, with the primary line of evidence coming from the toxicity test results themselves. AVS-SEM data are anticipated to assist in understanding the toxicity test results.

12.3.2 Decision Rules for Risk Questions to Assessment Endpoint No 2

Six measurement endpoints have been selected to assess the effects of sediment- and soil-derived COPECs on the survival, growth, and reproduction of birds and mammals at LHAAP, as presented in **Table 12-2**. It should be noted that some risk questions apply to either birds or mammals, but not both, because the exposure pathway may only be a concern for measurement receptors in one group or the other. Each measurement endpoint has an associated risk question and testable hypothesis from which specific decision rules can be derived, as follows.

Risk Question 2-1: Does the consumption, by birds, of COPEC concentrations in freshwater aquatic invertebrates, estimated using site-specific laboratory-based bioaccumulation tests, infer reduced survival, growth, or reproduction for birds at LHAAP?

Testable Hypothesis 2-1: EEQs calculated during the BERA using site-specific sediment-to-invertebrate uptake factors and food web models are below the threshold of concern for birds at LHAAP.

Decision Rule 1: If Testable Hypothesis 2-1 is accepted, COPECs in sediment pose an acceptable hazard for birds that consume sediment invertebrates.

Decision Rule 2: If Testable Hypothesis 2-1 is rejected, COPECs in sediment may pose an unacceptable hazard for birds that consume sediment invertebrates.

Risk Question 2-2: Does the consumption, by mammals, of COPEC concentrations in field-collected terrestrial plants infer reduced survival, growth, or reproduction for mammals at LHAAP?

Testable Hypothesis 2-2: EEQs calculated during the BERA using site-specific soil-to-plant uptake factors and food web models are below the threshold of concern for mammals at LHAAP.

Decision Rule 1: If Testable Hypothesis 2-2 is accepted, COPECs in soil pose an acceptable hazard for mammals that consume terrestrial plants.

Decision Rule 2: If Testable Hypothesis 2-2 is rejected, COPECs in the soil may pose an unacceptable hazard for mammals that consume terrestrial plants.

Risk Question 2-3: Does the consumption, by birds and mammals, of COPEC concentrations in laboratory-measured earthworms infer reduced survival, growth, or reproduction for birds and mammals at LHAAP?

Testable Hypothesis 2-3: EEQs calculated during the BERA using site-specific soil-to-earthworm uptake factors and food web models are below the threshold of concern for birds and mammals at LHAAP.

Decision Rule 1: If Testable Hypothesis 2-3 is accepted, COPECs in soil pose an acceptable hazard for birds and mammals that consume terrestrial invertebrates.

Decision Rule 2: If Testable Hypothesis 2-3 is rejected, COPECs in soil may pose an unacceptable hazard for birds and mammals that consume terrestrial invertebrates.

Risk Question 2-4: Does the consumption, by birds and mammals, of cumulative COPECs in diet, plus incidental surface water, soil, and sediment ingestion, infer reduced survival, growth, or reproduction for birds and mammals?

Testable Hypothesis 2-4: EEQs based on COPECs in diet, plus incidental surface water, soil, and sediment ingestion, are below the threshold of concern for birds and mammals at LHAAP.

Decision Rule 1: If Testable Hypothesis 2-4 is accepted, COPECs in site media pose an acceptable hazard for birds and mammals.

Decision Rule 2: If Testable Hypothesis 2-4 is rejected, COPECs in site media may pose an unacceptable hazard for birds and mammals.

It should be noted that Risk Question 2-4 is included as an assessment of cumulative hazard from all exposure pathways that are included in the revised food chain models, not just the COPEC dose from individual pathways (e.g., the ingestion of soil invertebrates, etc.).

Risk Question 2-5: Does the consumption, by birds and mammals, of trivalent chromium (Cr) and hexavalent Cr in diet, plus incidental soil ingestion, infer reduced survival, growth, or reproduction for birds and mammals?

Testable Hypothesis 2-5: EEQs based on trivalent Cr and hexavalent Cr in diet, plus incidental soil ingestion, are below the threshold of concern for birds and mammals, using results from site-specific Cr speciation soil sample results.

Decision Rule 1: If Testable Hypothesis 2-5 is accepted, trivalent Cr and hexavalent Cr in site soil pose an acceptable hazard for birds and mammals.

Decision Rule 2: If Testable Hypothesis 2-5 is rejected, trivalent Cr or hexavalent Cr in site soil may pose an unacceptable hazard for birds and mammals.

Risk Question 2-6: Does the consumption, by small mammals, of COPECs in diet, plus incidental soil ingestion, infer reduced reproduction for mammals at LHAAP?

Testable Hypothesis 2-6: Established biologically significant Rodent Sperm Analysis (RSA) thresholds for effect (i.e., for reproductive capability) are not exceeded.

Decision Rule 1: If Testable Hypothesis 2-6 is accepted, COPECs in site soil pose an acceptable hazard for mammals.

Decision Rule 2: If Testable Hypothesis 2-6 is rejected, COPECs in site soil may pose an unacceptable hazard for mammals.

12.3.3 Decision Rules for Risk Questions to Assessment Endpoint No 3

Assessment Endpoint No. 3 (Protection of terrestrial plant and invertebrate populations (base-of-the-food-chain receptors) is presented at the request of stakeholders; however, it has been agreed to by all parties that no Installation cleanup for the protection of base-of-the-food-chain receptors is necessary. Therefore, no measurement endpoints, risk questions, or testable hypotheses are proposed.

12.4 Work Plans and Sampling and Analysis Plans

This section presents a summary of work plans and SAPs that were prepared to collect site-specific field data to be used in the BERA.

12.4.1 Summary of Chromium Speciation Work Plan

Soil Sampling for Chromium Speciation in Soil (Shaw, 2006c) was prepared to determine existing Cr speciation (e.g., chromium VI [Cr^{VI}] and chromium III [Cr^{III}]) in soil at possible chromate source areas and non-chromate source areas at LHAAP. This information is used to refine the evaluation of Cr in soil in the BERA. Cr^{III} concentrations were estimated by subtracting Cr^{VI} concentrations from total Cr concentrations measured in individual soil samples.

A spatial analysis was performed by identifying all possible Cr^{VI} source areas at LHAAP, based on a detailed review of operational history. The locations of 14 identified buildings suspected of being possible Cr^{VI} source areas, due to chromate use or release, were plotted to show the proximity of these possible source areas relative to the locations of elevated detections of total Cr

in soil samples previously collected at the Installation (Shaw, 2006c). Based on this information, three areas were found where elevated concentrations of total Cr in soil were close to a possible Cr^{VI} source area, and these areas were recommended in the Work Plan (Shaw, 2006c and Figures 1-1 and 1-2 in Shaw, 2006c) for the collection of nine samples and Cr speciation. An additional nine samples were recommended for collection at areas not known to be related to CR^{VI} source areas.

12.4.2 Summary of BERA Work Plan

The LHAAP Field Sampling Work Plan (Shaw, 2006b) presented the approach for the further investigation of the chemicals identified as final COPECs at LHAAP following Step 3 of the 8-Step ERA process. The primary objectives of the BERA work plan were to collect site-specific data related to the uptake of final COPECs to plants, earthworms, and aquatic invertebrates that are prey items for various ecological receptors, establish a determination of toxicity to benthic invertebrates from final COPECs in sediment, and determine sediment COPEC bioavailability. To accomplish these objectives, the work plan proposed the collection of soil samples from the Industrial and Waste sub-areas, and sediment samples from the Goose Prairie Creek watershed and Cove area of Caddo Lake. Sample locations were selected using historical data to ensure that areas of suspected contamination were represented and to try to ensure that field study results would be based on a range of final COPEC concentrations. Co-located soil and plant tissue samples were proposed for both the Industrial and Waste sub-areas to determine the degree of uptake of final COPECs from soil into plants that may be ingested by herbivorous ecological receptors. Uptake into earthworms and aquatic invertebrates from soil and sediment final COPECs, respectively, was determined by introducing the organisms into the collected soil or sediment samples in a laboratory, and then measuring the tissue concentrations following a 28-day exposure period. A determination of the toxicity of final COPECs to benthic invertebrates was achieved by evaluating survival and growth of the amphipod *Hyalella azteca* following a 10-day laboratory exposure to sediment samples collected from LHAAP. Sediment COPEC bioavailability was determined using the AVS-SEM analytical technique.

12.4.3 Summary of Rodent Sperm Analysis Work Plan

The Rodent Sperm Analysis Study Statement of Work was prepared by USACHPPM (2003) to describe the application of the RSA field technique at LHAAP. The results of the study were intended to be used to supplement the Installation-wide ERA. RSA is a patent-pending method designed to bring ERAs at sites such as LHAAP to closure by providing as definitive a determination of receptor health as is possible at the present time. RSA is a sensitive testing procedure that borrows from established methods that are applied daily in research and clinical laboratory settings. In short, sperm parameters (such as sperm count) in field-collected rodents are assessed because they are barometers of reproductive success (the preferred toxicological

endpoint in ERAs). It is known that exposure to a number of chemical classes including dioxins, PCBs, pesticides such as DDT, DDE, and DDD, and certain metals can affect functional reproductive development (Gray et al., 1992). Many of these environmental contaminants are present at Plant 2. It has also been known that exposure to very low doses of dioxins produces infertility in rodent progeny (USACHPPM, 2006).

For the RSA at LHAAP, three study sites with known or suspected contamination, located in the north-central portion of the Industrial Sub-Area, were selected. These sites were the Plant 2 Area, a Wetland Area, and the Goose Prairie Creek Drainage. The field-applied RSA proposed trapping 15 adult male rodents of at least one species at both a study site and its matched reference location. Capturing sufficient adult male rodents was proposed by saturating a series of 100 meter by 100 meter grids with baited Sherman live traps. Established biologically significant (as opposed to statistically significant) sperm parameter thresholds for effect (i.e., each a barometer of reproductive success) were to be used in comparing the sperm of adult male rodents captured on site and at a nearby matched reference location.

BERA Assessment and Measurement Endpoints: Risk Questions and Testable Hypotheses

Table 12-1
Summary of BERA Assessment and Measurement Endpoints

Proposed Assessment Endpoints	Step 3 Receptors (Surrogate Species)	Step 3 Measurement Endpoints (Results)	BERA Measurement Endpoints Based on Site-Specific Field Work	BERA Measurement Endpoint Details for Site-Specific Bioaccumulation Approach
AE-1: Survival, growth, or reproduction of aquatic biota living in sediment	Freshwater sediment invertebrates-chironomids, amphipods (aquatic biota)	Comparison of site COPEC data to SQB	• Laboratory sediment invertebrate toxicity tests (freshwater amphipods) • Acid Volatile Sulfides - Simultaneously Extracted Metals (AVS - SEM) test to assess bioavailability	No bioaccumulation approach needed for this assessment endpoint.
AE-2: Survival, growth, and reproduction of birds and mammals	• American woodcock (-) • Deer mouse (-) • Short-tailed shrew (-) • Raccoon (-) • Louisiana Black Bear (Raccoon) • Rafinesque's Big Eared Bat (Townsend's Big Eared Bat)	• Intake/food-chain model EEQ estimation with generic bioaccumulation factors and total chromium assumed to be hexavalent chromium (some EEQs >1)	• Intake/food-chain model EEQ with site-specific bioaccumulation factors • Intake/food-chain model EEQ with site-specific chromium speciation data • Reproduction of mammals assessed using results of rodent sperm analysis technique	• Plant bioaccumulation estimated using co-located soil and plant samples • Sediment invertebrate bioaccumulation estimated using laboratory bioaccumulation study (freshwater aquatic worms) • Soil invertebrate bioaccumulation estimated using laboratory bioaccumulation study (earthworms)
AE-3: Protection of terrestrial plant and invertebrate populations (base of the food chain receptors)	Terrestrial plant and invertebrate communities	Comparison of site COPEC data to plant and invertebrate direct-contact toxicity benchmarks	None	No bioaccumulation approach needed for this assessment endpoint

Notes and Abbreviations:

For details regarding USEPA Step 4 Measurement Endpoints-measures of effect and exposure, USEPA Step 3b Risk Questions, and USEPA Step 4 Testable Hypotheses, please see Table 12-2.
AE-3 is presented as requested by stakeholders, however, it has been agreed that no Installation cleanup for the protection of base of the food chain receptors is necessary.

AE *assessment endpoint*
BERA *baseline ecological risk assessment*
COPEC *chemical of potential ecological concern*
EEQ *ecological effects quotient*
SQB *sediment quality benchmark*
USEPA *U.S. Environmental Protection Agency*

(-) denotes no surrogate species necessary, as the selected receptor has the minimum data requirements for quantification of the assessment and measurement endpoints

Table 12-2
BERA Assessment and Measurement Endpoints: Risk Questions and Testable Hypotheses

USEPA Step 3: Assessment Endpoint	USEPA Step 4: Measurement Endpoint—Measures of Effect and Exposure	USEPA Step 3b: Risk Questions USEPA Step 4: Testable Hypotheses
AE-1: Survival, growth, or reproduction of aquatic biota living in sediment	ME 1-1: Laboratory survival, growth, or reproduction of sediment-dwelling freshwater invertebrates (*Hyalella azteca*) in samples of site and reference location sediment (note: reference location upstream or in non-LHAAP impacted area of Caddo Lake)	ME 1-1 Risk Question: Does exposure to site sediment cause reduced survival, growth, or reproduction for invertebrates in sediment? ME-1-1 Testable Hypothesis: Means of laboratory survival, growth, or reproduction for invertebrates in site and reference location or control sediment are not significantly different. Note: Mean survival of the laboratory control for test species must equal or exceed 80 percent for results to be considered valid.
	ME 1-2: Acid Volatile Sulfides - Simultaneously Extracted Metals (AVS - SEM) data from sediment samples collected from the site and calculation of AVS – SEM ratio to assess bioavailability	ME 1-2 Risk Question: Are metal COPECs bioavailable such that exposure to site sediment causes reduced survival, growth, or reproduction for invertebrates in sediment? ME 1-2 Testable Hypothesis: Most of the AVS – SEM ratios in the samples (e.g., > 50%) are greater than 1 (i.e., SEM – AVS < 0), suggesting low bioavailability of metals.
AE-2: Survival, growth, and reproduction of birds and mammals	ME 2-1: Survival, growth, and reproduction of birds represented by the bank swallow and belted kingfisher based on consumption of sediment-dwelling aquatic invertebrates containing COPEC concentrations modeled from sediment-to-invertebrate relationship for COPECs for laboratory-measured concentrations of COPECs in samples of aquatic worms (*Lumbriculus variegatus*) and sediment from the site	ME 2-1 Risk Question: Does the consumption of COPEC concentrations in laboratory-measured freshwater aquatic worms by birds infer reduced survival, growth, or reproduction for birds? ME 2-1 Testable Hypothesis: EEQs are below the risk thresholds for birds.
	ME 2-2: Survival, growth, and reproduction of mammals represented by the deer mouse, Townsend's big-eared bat, and raccoon based on consumption of plants containing COPEC concentrations modeled from soil-to-plant relationship for COPECs for measured concentrations of COPECs in co-located field samples of plants and soil from the site	ME 2-2 Risk Question: Does the consumption of COPEC concentrations in field-collected plants by mammals infer reduced survival, growth, or reproduction for mammals? ME 2-2 Testable Hypothesis: EEQs are below the risk thresholds for mammals.

13.0 Step 5: Field Verification of Sampling Design

Verification of the field sampling design is Step 5 of the eight-step ERA process (USEPA, 1997a). However, due to the numerous site visits that have occurred at LHAAP over the past several years, an additional site visit to verify the field sampling design was not necessary. Minor changes to the field program were made in the field, as discussed in **Section 14.2**.

14.0 Step 6: Site Investigation

Section 14.0 presents the results of the site investigation.

14.1 Chromium Speciation Data Collection and Analysis

Soil samples for Cr speciation were targeted for collection at three possible chromate source areas, as well as at an equal number of non-source areas. This approach allowed a comparison of the Cr ratios (i.e., ratio of Cr^{III} to Cr^{VI}) between possible Cr^{VI} source areas and non-source areas. Based on the soil sampling scheme (Shaw, 2006c), the following null hypothesis (H_0) was formulated:

- H_0: The Cr ratio is statistically similar between soil samples collected at possible Cr^{VI} source areas and in soil samples collected at areas not suspected of being Cr^{VI} source areas

If H_0 is accepted then an average Cr ratio would be calculated and used for the BERA.

If the result of an appropriate statistical test is less than $P_{0.05}$ (i.e., a statistical difference does exist) then the H_0 will be rejected and the alternative hypothesis (H_1) will be accepted, which can be stated as follows:

- H_1: The Cr ratio is not statistically similar between soil samples collected at possible Cr^{VI} source areas and at soil samples collected at areas not suspected of being Cr^{VI} source areas

If H_1 is accepted then two separate Cr ratios would be calculated and used for the BERA.

To determine the Cr speciation in soil at the site, Shaw collected surface soil samples in each of the three areas of possible chromate soil contamination (Buildings B-16, 68-C, and 24-X) (**Figures 14-1** and **14-2**) on April 25, 2006 for a total of eight samples from possible chromate source areas. It should be noted that one soil sample (ERA-SS-05) could not be collected due to the presence of pavement. An additional nine surface soil samples were also collected on April 25, 2006 from other areas of the site not suspected of being possible chromate source areas, but that had elevated total Cr detections in the past. Each of the surface soil samples was collected from 0 to 1 foot depth bgs. Soil samples were analyzed for total Cr and Cr^{VI} using EPA Methods 6010B and 3060/7196A, respectively. Data are presented in **Appendix L**.

Cr speciation results are summarized in **Table 14-1**. Total Cr collected at possible chromate source areas ranged from 11.3 to 69.8 mg/kg and averaged 35.2 mg/kg, while Cr^{VI} ranged from non-detect to 0.59 mg/kg. Total Cr collected at non-chromate source areas ranged from 10.8 to

70.6 mg/kg and averaged 34.8 mg/kg, while Cr^{VI} was not detected in any sample. Cr^{III} was estimated by subtracting Cr^{VI} from total Cr results.

The Cr^{III} to Cr^{VI} ratio was estimated for each sample by dividing Cr^{III} by Cr^{VI}. The Cr^{III} to Cr^{VI} ratio at possible chromate source areas ranged from 19.3 to 145 and averaged 74, while the Cr^{III} to Cr^{VI} ratio at non-chromate source areas ranged from 17.9 to 126 and averaged 67. There was considerable overlap between the 95 percent confidence intervals for the Cr^{III} to Cr^{VI} ratios for the two areas, as shown in **Figure 14-3**, and there was no significant difference between the two ratios (t-test, $p > 0.05$).

As there was no significant difference in the Cr ratios between the possible Cr^{VI} source areas and the other areas, it was concluded that there is no reason to establish a separate Cr^{III} to Cr^{VI} ratio at the possible chromate source areas. Thus, the soil sample results from all sampled locations were combined, and an average site-specific Cr ratio of 70:1 was calculated for LHAAP and is used in the BERA for all total Cr soil data. This Cr^{III} to Cr^{VI} ratio is considerably greater than the 6:1 ratio commonly recommended by regulatory guidance as a default assumption for risk assessments; however, because approximately half of the samples used to develop this ratio were purposefully located near suspected Cr^{VI} source areas, this ratio is expected to be a conservative estimate of the ratio across the Installation as a whole. By replacing the 6:1 ratio assumption with the 70:1 ratio based on site-specific data, it is assumed that concentrations of Cr^{VI} in soil at LHAAP are approximately 1.4 percent of the total Cr concentrations.

In conclusion, the site-specific determination of Cr speciation in LHAAP soil samples substantially reduced the initial conservative estimate of Cr^{VI} assumed to be present. Even though several areas of chromate use have been documented at the site, Cr^{VI} was found to be present at very low concentrations, likely due to environmental transformation and degradation over time. Use of the site-specific Cr^{III} to Cr^{VI} ratio of 70:1, compared with the conservative default assumption of 6:1, reduces the previously estimated concentrations of Cr^{VI} by approximately 10-fold in LHAAP soil.

14.2 BERA Data Collection and Analysis

Collection of field data for the LHAAP BERA took place October 3 to 6, 2006. The field work was conducted in accordance with the *Final Baseline Ecological Risk Assessment Field Sampling Work Plan* (Shaw, 2006b). A few deviations from the Work Plan occurred during field sample collection, summarized as follows:

- One proposed soil sample location in the LHAAP-04 area (STEP-04SS06-BERA-SS05) was relocated to LHS-MW50-BERA-SS05 (south of LHAAP-47) because it was noted by USFWS personnel during the field event that the sample location had been the site of a pilot perchlorate bioremediation study, and therefore was not an appropriate BERA sample location.

- All proposed sediment sample locations were dry except for the background reference location in Clinton Lake due to the pervasive drought conditions that occurred before and during the field sampling. After consultation with USFWS, it was decided to collect sediment samples as planned and have the bioassay laboratory re-hydrate the sediments in the lab. It should be clarified that here and in the rest of the BERA, the term "dry" sediment samples refers to the fact that the samples were not covered by water at the time of collection; however, the sediment samples themselves ranged from moist to saturated.

- A total of twelve sediment samples (six from Goose Prairie Creek watershed, and six from Goose Prairie Creek Cove in Caddo Lake) were sent to the laboratory for rapid turnaround chemical analyses for metals. As described in the Work Plan (Shaw, 2006b), a subset of samples to use for the BERA uptake factor and toxicity tests was selected based on the detected concentrations of metal final COPECs. This approach was used to obtain a range of concentrations for each metal to maximize information that could be used to determine uptake and toxicity. Based on the rapid turnaround analytical results, five sediment samples were selected from the north and south Goose Prairie Creek Cove of Caddo Lake and three sediment samples were selected from the Goose Prairie Creek watershed. This represents a slight deviation from the work plan, which indicated that four samples would be collected from the Coves and four would be collected from the Goose Prairie Creek watershed.

- Historic LHAAP Goose Prairie Creek Watershed and Caddo Lake surface water data were used to determine the hardness of the water used by the bioassay laboratory to run the sediment toxicity and bioaccumulation tests because surface water was not present at most sample locations during the field event, which prohibited a determination of water hardness conditions from field samples. Historic data indicated the following: (1) an average water hardness of 31 mg/L for the general Goose Prairie Creek Cove sediment sample area from 1998 through 2006 (Darville, 2006); and (2) an average water hardness of 47 mg/L for the Goose Prairie Creek sediment sample areas. A hardness of 19 mg/L was indicated for the Clinton Lake background reference sample, based on a combination of current site-specific data and historic data.

- When the bioassay laboratory (see **Appendix N**) originally rehydrated the eight selected sediment samples, the overlying water was found to have an unexpectedly low pH (i.e., a range of approximately 3.5 to 4.1 for the cove sediment samples and a pH range of approximately 5.4 to 5.8 for the Goose Prairie Creek stream sediment samples, excluding background). These low pH conditions are thought to be related to the unusual drought conditions (Warren et. al., 2001; Van Haesebroeck et al, 1997; and Clark et al., 2005). In addition, the concentrations of sulfate in the sediment, which is thought to be naturally-occurring, were inversely correlated with the overlying water pH, suggesting that sulfates were responsible for the low pH conditions. Because the optimal pH range for the bioassay toxicity test organism (*Hyalella*) is 6 to 9, the bioassay laboratory performed overlying water changeouts as stipulated by the test method (ASTM, 2000; USEPA, 2000b) to obtain an overlying water pH of at least 6 prior to initiating the test. Water changeouts were conducted

twice per day for two days for both the stream and cove sediment samples. The overlying water, however, became more acidic over time, dropping below a pH of 6 for some sediment samples during the toxicity tests. As this low pH condition would be expected to result in test organism toxicity, the lake sediment toxicity tests were re-initiated using water with a hardness of 88 mg/L. This hardness is the standard hardness the bioassay laboratory typically uses for freshwater tests and represents the optimal hardness preference for the *Hyalella* organisms. This harder water was expected to buffer the pH such that overlying water remained above a pH of 6. The original toxicity tests, however, were completed for informational purposes to estimate potential toxicity due to low pH using water that matched the site-specific hardness values. It should be noted that monitoring data from Caddo Lake (1998 to 2005) shows typical surface water pH that ranges from approximately 6 to 7 (Darville, 2006). Although the adjusted water hardness used in the *Hyalella* sediment toxicity test was not identical to the field conditions (i.e., the adjusted water hardness was higher than the estimated field conditions due to an adjustment necessary to account for the unique drought conditions during the BERA field work), the toxicity test results have utility for this assessment.

Hyalella survival rates in control samples from the original toxicity tests for the creek sediment samples were acceptable (> 80 percent), but high mortality was experienced by all test organisms in the lake sediment samples. Therefore, the results from toxicity tests with the adjusted overlying water hardness were used for the lake sediment samples, but the unadjusted overlying water hardness results were used for the creek sediment samples. A discussed in **Section 15.8.1**, the use of harder water for the lake sample toxicity tests may have resulted in lower toxicity than would be expected under natural conditions, but the presence of AVS that would be expected under normal (i.e. non-drought) conditions would likely offset this higher toxicity to some extent, if not completely.

- The test organism used for the sediment bioaccumulation test was *Lumbriculus*, which tends to be more tolerant of lower pH conditions than *Hyalella*. Also, because the water-to-sediment ratio used in these tests is greater than in the toxicity tests, it was not expected that acidification of the overlying water by the low-pH sediment would occur, as it did in the toxicity tests. Therefore, the bioaccumulation tests were run using water renewal conditions that matched the site-specific hardness of ambient soft waters so that conditions affecting metals bioavailability conditions were replicated as much as possible.

Site-specific terrestrial (i.e., soil-to-earthworm and soil-to-plant) and aquatic (i.e., sediment-to-invertebrate) uptake factors were developed from the collected data to quantify transport of chemicals from site media to biotic organisms that may be ingested as prey or forage items by BERA ecological receptors. If the data were adequate for the development of site-specific uptake factors, they were used in place of literature values used for the Tier 1 food chain modeling exercise (**Section 7.2, Volume I**) to develop new EEQs. **Table 14-2** presents the list

of samples that were collected as part of the BERA investigation. All data were validated prior to use.

Concentrations of final COPECs in the co-located abiotic and biotic samples were compared, and a simple ratio consisting of the tissue concentration divided by the abiotic medium concentration was developed for each sample location. If the final COPEC was detected in one medium (e.g., soil) but not the other (e.g., earthworm tissue), the concentration in the non-detect result was estimated as being equal to one-half the MDL. Ratios were not developed for sample pairs where both the tissue and abiotic samples were non-detect. The arithmetic mean of all sample location ratios for a given chemical was then calculated as a candidate for use as a site-specific BAF.

Single-value uptake factors assume that the concentration of chemicals in organisms is a linear, non-threshold function of concentrations in abiotic media. However, for chemicals that are regulated or metabolized by the organism, the degree of uptake (and retention) in an organism may vary depending on the concentration in the abiotic medium. Also, threshold concentrations may exist below which bioaccumulation does not occur (Sample et al., 1999). Simple linear regression models that may account for some of these factors were developed for final COPECs if the dataset was considered sufficiently robust, based on professional judgment. Regression equations were developed using natural log-transformed data. The tissue concentration was assigned as the response (i.e., dependent) variable, and the abiotic concentration was assigned as the explanatory (i.e., independent) variable. A best-fit linear regression equation was generated and plotted. Both terrestrial (i.e., soil-earthworm and soil-plant) datasets had a sample size (n) of 10. Significance of the model was determined using two criteria. First, overall model significance was determined by the statistical significance of the model's F factor. The null hypothesis for this test is that the slope of the model is not significantly different from zero. If the F factor was significant at a $P_{0.05}$ level (i.e., $p < 0.05$), then the alternative hypothesis, that the slope is significantly different from zero, was adopted. Second, the amount of variability the model accounted for (i.e., the strength of the model's ability to predict the tissue concentration from the soil or sediment concentration), as reflected by the coefficient of determination (R^2), was tested for significance. The threshold of significance ($P_{0.05}$) for a dataset depends on the degree of freedom, which is calculated as sample size (n) minus 2 for linear regression models. For the soil dataset, which had a sample size of 10, the threshold of significance with 8 (i.e., 10 minus 2) degrees of freedom is an R^2 value of 0.399 or higher (Steel and Torrie, 1980). For the aquatic dataset, which had a sample size of 8, the threshold of significance with 6 (i.e., 8 minus 2) degrees of freedom is an R^2 value of 0.500 or higher. Regression equations that met these two criteria (i.e., the overall model significance and the acceptability of the R^2 value) were considered as candidates for use as uptake factor, in place of single-point uptake values. Use of these two criteria is based on the regression uptake approach employed by USEPA (2005)

(Attachment 4-1 *Exposure Factors and Bioaccumulation Models for Determination of Wildlife Eco-SSLs*). All data analyses were performed using Microsoft Excel® software.

Discussions regarding the data evaluation and use for various media and exposure pathways are presented in the sections that follow. Further discussions and final selection of BAFs used in the BERA for final COPECs are provided in **Section 14.2.4**. The analytical data used to develop site-specific uptake factors are presented in **Appendix M**. Complete data results for all samples collected during the BERA field investigation are presented in **Exhibit 1, Data Report** (Compact Disk 2).

14.2.1 Soil to Earthworm Bioaccumulation – Data Collection and Analysis

Five metal (barium, cadmium, Cr, lead, and zinc) and three explosive (2,4-DNT, 2,6-DNT, and TNT) final COPECs were selected for refinement for the soil-to-earthworm pathway in the BERA (**Table 11-1, Volume I**). Ten soil/tissue sample pairs were used to develop site-specific uptake factors in earthworms (five from the Industrial Sub-Area and five from the Waste Sub-Area) for the metal final COPECs, and five soil/tissue sample pairs (all from the Waste Sub-Area) were used to develop site specific soil-to-earthworm uptake factors for the explosives final COPECs (**Table 14-2**).

The uptake factor ratios for the individual sampling locations and the arithmetic mean of the ratio, are presented in **Table 14-3** and **14-4** for metals and explosives, respectively. For metals, all ratios were based on detected concentrations in both the tissue and the soil. However, for Cr, all tissue concentrations were B-qualified, indicating that the tissue concentration was not distinctively different from the blank concentration, using the 5-times rule invoked in data validation. Therefore, there is some question as to whether any bioaccumulation of Cr is taking place in soil invertebrates. However, as a conservative approach, uptake factors were calculated using the B-qualified data without adjustment (i.e., the samples were treated as detections, rather than as non-detects). For explosives, only one tissue sample had a detection of any of the three final COPECs (TNT at location 17SB02-BERA-SS09). Seven other tissue/soil sample pairs had detects in soil, but not for tissue. For these non-detect tissue samples, the MDL for tissue was comparable to that for soil, and the use of one-half the MDL as a surrogate concentration in tissue was considered appropriate for these sample pairs.

Only the metal bio-uptake data were considered robust enough for regression analysis (n = 10). The datasets for barium, cadmium, and lead resulted in significant regression equations using the criteria described previously (**Table 14-5**). The full results of the statistical regression analysis are presented in **Appendix M**.

14.2.2 Soil to Plant Bioaccumulation - Data Collection and Analysis

One metal (barium), perchlorate, and three explosives (2,4-DNT, 2,6-DNT, and TNT) were selected for refinement in the soil-to-plant pathway in the BERA (**Table 11-1, Volume I)**. Ten soil/tissue sample pairs were used to develop site-specific uptake factors in plants (five from the Industrial Sub-Area and five from the Waste Sub-Area) for the metal final COPECs, and five soil/tissue sample pairs (all from the Waste Sub-Area) were used to develop site specific soil-to-plant uptake factors for the explosives final COPECs (**Table 14-2**). Five soil/tissue sample pairs from the Industrial Sub-Area were also used to evaluate perchlorate, which was considered a final COPEC due to uncertainty regarding its toxicity and uptake properties in plants.

The uptake factor ratios for the individual sampling locations, and the arithmetic mean of the ratios, are presented in **Tables 14-6** and **14-7** for metals and explosives, respectively. For metals, all ratios were based on detected concentrations in both the tissue and soil. For lead, two tissue concentrations were B-qualified, indicating that the tissue concentration was not distinctively different from the blank concentration, using the 5-times rule. As a conservative approach, uptake factors were calculated using the B-qualified data without adjustment. For explosives, only one tissue sample had a detection of any of the three final COPECs (2,4-DNT at location 17SD07-BERA-SS06). Seven other tissue/soil sample pairs had detects in soil, but not for tissue. However, for these sample pairs that had non-detect concentrations in tissue, all soil concentrations were low (J-qualified), and the tissue MDL was highly elevated compared with the detected soil concentrations. In some cases (e.g., location 17SD07 for 2,6-DNT, and 17SD07 and 17SB04 for TNT), the MDL was one-and-a-half to two orders of magnitude greater than the soil concentration. Because the MDL is used in the numerator for sample pair BAF ratio calculations, this results in elevated BAF ratios that are driven by the MDL rather than by actual (i.e., detected) tissue concentrations. Therefore, the soil-to-plant uptake factors for explosives are considered highly uncertain. The implications of this finding are discussed further in **Section 14.2.4**.

For perchlorate, only one tissue/soil sample pair had a detected concentration of perchlorate. Perchlorate was detected in the leaves of a slippery elm (*Ulmus rubra*) tree at location 25C-56 at a concentration of 189 mg/kg. It was detected in the co-located 2006 soil sample (0 to 0.5 foot depth) at an estimated concentration of 0.0132 mg/kg, which would result in an uptake factor of 14,318. Historical surface soil (0 to 0.5 foot depth; sample 25C-56[1]) and deeper surface soil (1 to 2 foot depth; sample 25C-56[2]) samples collected in 1999 from this location had perchlorate concentrations of 1.8 and 39 mg/kg, respectively. One of perchlorate's trademark characteristics from a fate-and-transport perspective is its extremely high solubility in water. The fact that concentrations were greater in the historical sample collected from a depth of 1 to 2 feet compared with the 0-0.5 foot sample, and the fact that the shallow soil sample collected 7 years ago was more than two orders of magnitude greater than the (2006) BERA soil sample,

suggest that perchlorate is being transported vertically downward as the result of percolation of rain water. Because of the somewhat transient nature of perchlorate in surface soil, a soil-to-plant uptake factor based on the shallow BERA soil sample would be biased high, because the very low concentration in that sample does not reflect the soil concentrations that resulted in the transport and retention in the tree plant leaves over time. Furthermore, perchlorate was measured in the leaves of trees because indirect ingestion of tree leaves by bats (via ingestion of moths, whose larvae are assumed to eat exclusively tree leaves) was assumed to be the pathway of greatest ecological concern for this chemical (Shaw, 2006b). Tree roots can extend many feet underground and concentrations of perchlorate at a depth of 0 to 0.5 feet probably do not reflect the concentration that is available for uptake by trees. If the historical soil sample (measured in 1999) from the 1 to 2 foot sampling interval is used in conjunction with the concentration detected in the BERA plant tissue sample, the resultant uptake factor is 4.8 (i.e., 189 mg/kg in plant tissue divided by 39 mg/kg in soil). This uptake factor is comparable to the uptake factor that was estimated using the regression equation specified in the Tier 1 modeling (see **Table 7-20** in **Volume I**), which was approximately 6.6 (based on the Industrial Sub-Area shallow soil EPC). Because of the small sample size (n = 1), and the likelihood that perchlorate in shallow surface soil is not highly correlated with concentrations in the co-located plant tissue due to vertical migration of the chemical and a spatial disconnect of the depths of the tree roots compared with the 2006 sampling depth, it was determined that the development of a site-specific uptake factor for perchlorate was not appropriate based on data collected during the BERA. Rather, the finding that an uptake factor calculated using the deeper historical soil data was considered as confirmatory of the accuracy of the regression equation that was used in the Tier 1 food chain model. Therefore, the Tier 1 soil-to-plant regression equation was selected to represent perchlorate uptake in the BERA.

Only the metal soil-to-plant bio-uptake data were considered robust enough for regression analysis (n = 10). However, the barium dataset did not result in a significant relationship between the concentration in soil and the concentration in plant tissue (Table 14-8, **Appendix M**). Therefore, the simple BAF based on BERA field data was used to estimate barium uptake by plants from soil.

14.2.3 Sediment to Aquatic Invertebrate Bioaccumulation - Data Collection and Analysis

Three metal final COPECs (lead, mercury, and thallium) were selected for refinement in the sediment-to-aquatic invertebrate pathway in the BERA (**Table 11-2**, **Volume I**). Eight sediment/tissue sample pairs were used to develop site-specific uptake factors for aquatic invertebrates. Three samples were collected in the Goose Prairie Creek watershed, and five were collected in the Goose Prairie Creek Cove area of Caddo Lake. Results for the watershed and lake locations were pooled for the purpose of developing uptake factors for the Installation as a whole.

The metal uptake factor ratios for the individual sampling locations, and the arithmetic mean of the ratios, are presented in **Table 14-9**. For lead, all ratios were based on detected concentrations in both the tissue and the sediment. All lead tissue concentrations were flagged with the validation qualifier JH, meaning the concentration is possibly biased high. Using high-biased tissue concentrations results in a conservative uptake factor ratio, because the concentration detected in the tissue (which appears in the numerator of the ratio) is likely to be higher than reported. For mercury, six of the eight ratios were based on detections in both tissue and sediment, but two sample pairs had non-detects in the tissue. One-half of the MDL was used as a surrogate for tissue concentrations in these two samples. For thallium, all tissue samples were non-detect. Therefore, there is some question as to whether any bioaccumulation of thallium is taking place in aquatic invertebrates. However, the maximum thallium concentration detected in the BERA sediment samples was 0.26 mg/kg, which is well below the MDC in the historical dataset for the Goose Prairie Creek watershed of 2.69 mg/kg (**Table 6-23, Volume I**). Thus, the degree of uptake associated with the upper range of historical concentrations is unknown. For purposes of the BERA it is assumed that thallium uptake is occurring, but to a relatively low degree that results in tissue concentrations below the detection limit of the method. For the non-detect tissue samples, the MDL for tissue was extremely elevated compared to the low (i.e., J-qualified) soil concentrations, which resulted in calculated BAF ratios ranging from 44 to 115. The elevated MDL was partly due to the relatively low percent solids of the aquatic worms, which decreased the ability of the analysis to detect concentrations in tissue. Therefore, little meaningful information can be obtained from the BERA data regarding aquatic invertebrate uptake of thallium. Due to this high degree of uncertainty, the BERA BAF data for thallium were not used, and the Tier 1 BAF (**Volume I**) was used instead.

The metal bio-uptake data for lead and mercury were considered robust enough for regression analysis (n = 8). A regression analysis was not conducted for thallium because all tissue samples were non-detect, and, therefore, the calculated uptake factors were simply a function of the MDL rather than the concentration in sediment. Only the lead analysis resulted in a significant regression equation (**Table 14-10**). Results of the statistical regression analysis are presented in **Appendix M**.

14.2.4 Summary of BERA BAFs

The BAFs that were selected to use in the BERA to model uptake from abiotic media into earthworms, plants, and aquatic invertebrates are presented in **Tables 14-11**, **14-12**, and **14-13**, respectively. These BAFs replaced the default literature-based BAFs used in the Step 3 food chain model (see **Section 7.2** in **Volume I**), and were used to calculate new EEQs for the BERA. Because of uncertainties associated with the data, site-specific BAFs for perchlorate and explosives for the soil-to-plant pathway, and the thallium sediment-to-aquatic invertebrate

pathway, were not adopted for use in the BERA, as previously discussed. The Tier 1 values that were previously used for these chemicals were carried forward for the BERA food chain model.

14.2.5 Sediment Toxicity - Data Collection and Analysis

Sediment sampling at the Installation was conducted by Shaw personnel from October 3 through 6, 2006. A total of 14 sediment samples were collected and placed in 4-liter wide-mouth plastic containers. The containers were labeled, packed on wet ice, and shipped by overnight delivery to Nautilus Environmental, Inc. (the bioassay laboratory). Split samples were sent to Severn Trent Laboratory for chemical analysis. Based on the rapid turnaround analytical metal results (see **Section 14.2**), five sediment samples were selected for toxicity testing from the north and south Goose Prairie Creek Cove of Caddo Lake and three sediment samples were selected from the Goose Prairie Creek watershed. In addition to these eight samples, reference samples from Clinton Lake and upstream on Goose Prairie Creek were also used for toxicity testing. Chemical analytical results are presented in the Data Report (**Exhibit 1)**.

H. azteca were exposed to test sediments for 10 days to determine the effects of site sediment on survival and growth. These tests were conducted according to methods presented in USEPA (2000b) and ASTM (2000). A complete report prepared by the bioassay laboratory (Nautilus Environmental, Inc.) is presented in **Appendix N**. Results of the toxicity tests conducted using *H. azteca* are provided in this appendix**,** including tables showing mean percent survival, mean growth, and results of the statistical analyses comparing responses in the sample locations to the responses in the laboratory control and reference sediments. Detailed results of the sediment toxicity tests, water quality measurements recorded during the tests, and the reference toxicant test results are provided in Attachments 1, 2 and 3, respectively, of **Appendix N**.

None of the Goose Prairie Creek sediment exhibited a statistically significant effect on amphipod survival compared to the laboratory control or reference sediment. The three creek sediments, as well as the reference sediment, had reduced growth compared to growth in the control sediment. However, none of the site sediment showed a statistically significant reduction in growth compared to the creek reference sediment.

One of the Goose Prairie Creek Cove (Caddo Lake) sediment samples, CL-GPSN-3-BERA-SD02, demonstrated reduced amphipod survival and growth compared to results of both the control and lake reference sediment samples, and also had a relative percent difference (RPD) in response greater than 20 percent. A RPD of 20 percent or greater is generally considered biologically significant (Suter et al., 2000). Another Goose Prairie Creek Cove (Caddo Lake) sediment sample, CL-GPSN-2-BERA-SD09, demonstrated a statistically significant reduction in growth compared to the control and reference sediment samples, but not in survival. In addition, the RPD was greater than 20 percent for growth. Growth in sediment sample CL-GPSS-3-

BERA-SD10 demonstrated a statistically significant reduction compared to the laboratory control sample, but not to the reference sediment sample.

Amphipod survival and growth are plotted against sediment COPEC concentrations in **Figures 14-4** and **14-5**, respectively. Sediment concentrations for lead, mercury, and silver are included in these two figures, as these three metals were identified as final COPECs for sediment due to concerns about direct toxicity to benthic vertebrates (**Table 11-2, Volume I**). As shown in **Figure 14-4**, amphipod survival is significantly lower in one sample location (CL-GPSN-3-BERA-SD02 in the Goose Prairie Creek Cove), and this location had the maximum concentration of lead (i.e., 352 mg/kg). Concentrations of the other two COPECs (mercury and silver) do not show corresponding maxima at this location. In addition, other locations with maximum concentrations of mercury and silver are not associated with reduced survival. These observations strongly suggest that these metals are not related to the observed sediment toxicity.

As shown in **Figure 14-5**, amphipod growth is significantly lower in two sample locations (CL-GPSN-3-BERA-SD02 and CL-GPSN-2-BERA-SD09 in the Goose Prairie Creek Cove), and at these locations the concentrations of lead are elevated (e.g., 352 and 246 mg/kg, respectively). Concentrations of the other two sediment COPECs (mercury and silver) do not show corresponding maxima at these locations. In addition, other locations with maximum concentrations of mercury and silver are not associated with reduced growth. These observations strongly suggest that these metals are not related to the observed sediment toxicity.

Based on this evaluation of sediment toxicity using site-specific test results, elevated concentrations of lead in the North Goose Prairie Creek Cove area of Caddo Lake appear to be related to the observed aquatic toxicity. It is important to note that North Cove samples were placed along a transect in the same locations of historical samples that exhibited elevated lead concentrations. This transect was directly in line with a duck blind located on the western shore of the cove. Therefore, it is possible that at least some of the lead in these samples could be from weathered lead shot deposited in the cove from past hunting events, rather than present as the result of previous on-site activities. To investigate this possibility further, concentrations of all metals detected in the BERA sediment samples from the North Goose Prairie Creek Cove area were sorted by their sample location. The three North Cove sediment sample locations CL-GPSN-2, -3, and -4 were approximately 190-, 150-, and 90-feet from the shore where the blind was located, respectively. Among the 18 metals that were detected at least once in these three samples, lead was the only metal that exhibited a maximum concentration at CL-GPSN-3. Interestingly, the distance of this sample location from the duck blind matches the typical range of shotguns of 50 yards (http:..www.answers.com/topic.shotgun). Although the range of a shotgun varies by the type of gun and shot that is used, the data suggest that the lead concentration pattern imitates the expected fallout distance of bird shot. It is acknowledged,

however, that other studies have identified an inverse relationship between overall lead concentrations in Caddo Lake and distance to the Installation (Shaw, 2004c).

14.2.6 Acid Volatile Sulfide Simultaneously Extracted Metals

In the Work Plan (Shaw, 2006b), the AVS-SEM analytical technique was proposed to evaluate the bioavailability of metal COPECs in sediment (**Sections 12.3.1** and **12.4.2**). However, AVS was found to be non-detect in all of the collected sediment samples (**Appendix M-2**). This finding is thought to be a direct result of the unusual drought conditions present during sediment sample collection. Studies by Van Griethuysen (2006) and Van Griethuysen et al. (2003) demonstrate that sediment AVS depletion and removal is caused by desiccation during periods of drought, and that it may take up to two to three months after conditions return to normal (i.e., saturated conditions) before sufficient AVS can be formed to bind SEM (i.e., metals such as lead). These studies also suggest that recruitment of benthic infauna may occur more quickly than AVS can be formed to bind with SEM. Therefore, for a short period of time, a window of potential toxicity may occur after the sediments are flooded and before AVS levels have returned to equilibrium.

This finding suggests that under normal saturated sediment conditions, levels of AVS are likely to be much greater at LHAAP than during the drought conditions present in the fall of 2006 when sampling was conducted for this BERA. Greater levels of AVS in sediment would be expected to result in much lower metals bioavailability, and therefore reduced sediment toxicity to sensitive benthic invertebrates. In other words, the sediment toxicity tests that were conducted for this BERA were conducted under "worst case" conditions with regard to the presence of AVS, and the observed toxicity in these tests are likely greater than the toxicity that would be expected under normal sediment conditions. The magnitude of toxicity reduction due to the presence of elevated AVS during normal (non-drought) conditions is not known, and this uncertainty is discussed further in **Section 15.7**.

14.3 Summary of RSA Data Collection and Analysis

Most of the information provided in this section related to the RSA Study is from USACHPPM (2006), which is presented in **Appendix P**. The RSA Work Plan and purpose of the study were previously discussed in **Section 12.4.3**.

Small rodent trapping occurred from January 12 to February 1, 2004 at LHAAP. Areas that were targeted included the Plant 2 Area, the associated Plant 2 Wetlands Area, the Goose Prairie Creek Drainage Area, and matched reference locations. **Figure 14-6** illustrates the locations of rodents with sperm that were trapped and used for the Study, while Figure D-1 in **Appendix D** shows the location of the matched reference location. The field work and data analysis were performed by USACHPPM with assistance from Shaw personnel. All trapped small rodents

were examined for overall health condition, identified to sex, species, and approximate age, and then weighed. All captures other than adult males had a small patch of fur at the back of the neck clipped so that recaptures could be identified. Only adult males were brought to the on-site mobile laboratory for additional weighing and work-up. The analytical procedures for the sperm parameters followed Tannenbaum et al. (2003b). In addition to the sperm parameter measurements (i.e., RSA's primary assessment metrics), the LHAAP field effort collected additional supplemental information. This information can be categorized as population- and tissue-based. The former includes total animal captures, relative abundance of animals and species, sex ratios, age distribution, and relative trap success. Tissue-based information includes animal body weights, several organ-to-body weight ratios, and a histological examination for kidney, liver, spleen, and epididymis. The population- and tissue-based information can often be used to corroborate the findings of the sperm parameters assessment.

14.3.1 RSA Findings

The two dominant small rodent species collected at the sites were the hispid cotton rat (*Sigmodon hispidus*) and the cotton mouse (*Peromuscus gossypinus)*, although a few individuals of golden mouse (*Ochrotomys nuttalli*) and marsh rice rat (*Oryzomys paulustris*) were also collected. A total of 1,500 trap nights occurred at Plant 2, 1,500 trap nights occurred at the Goose Prairie Creek Drainage Area, 600 trap nights occurred at the Wetland Area, and 2,700 trap nights occurred at the reference area. Hispid cotton rat captures were more than double the number of cotton mouse captures. Total hispid cotton rat captures at the three study sites (i.e., 47, 9, and 36 for the Plant 2, Goose Prairie Creek Drainage, and Wetland Area, respectively) generally exceeded captures in the reference area (i.e., 28) (USACHPPM, 2006; Deck, 2007), providing an indication that the condition of the study sites was not limiting to this species. Catch per unit effort results are presented below for the hispid cotton rat:

Area	**Plant 2**	**GPC Drainage**	**Wetland Area**	**Reference Area**
Total Captures	47	9	36	28
Trap Nights	1,500	1,500	600	2,700
Captures/Trap Night	0.031	0.006	0.060	0.010

Eleven out of the 15 hispid cotton rats at two of the three study sites had an adult appearance (size, weight), but lacked sperm entirely. Cotton mice were not nearly as numerous as the hispid cotton rats at the study sites or the reference areas; therefore, the sperm parameter comparisons for this species were only sufficiently robust for analysis at one of the sites. Almost all of the organ-to-body weight ratios for the hispid cotton rats were lower at the various study sites compared to the reference locations. However, it is important to note that no relationship has been documented between organ-to-body weight ratios and population level effects (USACHPPM, 2006).

14.3.2 RSA Discussion

One of RSA's principal assumptions is that if, after several decades of exposure to contaminated site media animals do not display evidence of reproductive impact, then it is reasonable to anticipate that future reproductive impacts will not arise (Tannenbaum et. al., 2003a). This principal assumption is built on two other assumptions. First, that rodents generally have the maximum and/or worse-case exposures of terrestrial receptors (principally mammals and birds). If rodent reproduction is proceeding adequately, then this should also be the case for other terrestrial receptors (i.e., those that have a decidedly lesser degree of contact with the contaminated terrestrial ecosystem than do rodents, and those that cannot be captured and sacrificed for study). Second, tracking reproduction as the only toxicological endpoint amounts to a sufficiently rigorous assessment scheme. If reproduction is proceeding adequately at a historically contaminated site (Tannenbaum, 2003), then this indicates that animals are able to live until they are sexually mature, find mates, and go on to produce viable young. Additionally, if a species continues to produce viable young at a historically contaminated site (e.g., LHAAP), this is reasonably interpreted to mean that no other biological function (e.g., behavior, neurology) is being compromised at a level of concern.

RSA is able to arrive at rather definitive determinations of terrestrial receptor health because it is known how much of a perturbation in the sperm parameters (i.e., count, motility, and morphology, all of which are barometers of reproductive health) is needed for there to be a condition of biological/ecological compromise. Further, because rodents produce 10-20 times more sperm than is necessary to ensure that adequate reproduction proceeds, as much as an 80 to 90 percent sperm count reduction is needed before a claim can be made of impaired reproduction at the population level. In the interest of maintaining conservatism when assessing the reproductive condition of field-collected rodents at contaminated sites, USACHPPM, based on supportive peer-reviewed documentation, elected to apply a 60 percent sperm count reduction as the "trigger" for possible compromised reproduction. The literature also reports that sperm motility needs to be approximately 40 to 50 percent reduced from the control condition (here, the sperm motility of the reference area) in order to claim a case of reproductive impact. Sperm morphology (abnormality) appears to be the most sensitive of the three sperm parameters; an increase of only 4 percent from the "control rate" (i.e., the frequency of abnormal sperm occurring in the background, or in the case of LHAAP, the reference area) is enough to conclude that reproductive compromise is occurring.

For LHAAP, none of the sperm parameter thresholds were exceeded for either the hispid cotton rat or the cotton mouse, nor were there any statistically significant differences for these comparisons. Several other sperm parameter measures routinely analyzed with RSA include progressive motility, path velocity, curvilinear velocity, straight-line velocity, and beat cross frequency. Although it has not been established that these parameters are barometers of

reproductive success (as are count, motility, and abnormality), the finding that there are no statistically significant differences between group means for these ancillary parameters provides corroboration that the reproductive system of the rodents is not ill-effected at the three LHAAP areas studied.

14.3.3 RSA Conclusions

For the hispid cotton rat (the dominant rodent species caught at LHAAP during the RSA Study), none of the established sperm parameter thresholds for effect were exceeded at the three study sites. The data are interpreted to mean that reproductive capability is not compromised in maximally exposed terrestrial receptors (small rodents) and by extension in other larger and wider-ranging mammals.

Corroboration for the finding of successful reproduction in mammals based on sperm parameters is provided by the similarity in total animal captures at the study sites and the reference areas, which suggests that fecundity is similar between the potentially contaminated sites and control areas.

As mentioned previously, 11 out of the 15 hispid cotton rats at the Plant 2 area had an adult appearance (size, weight), but were observed to have no sperm. However, in light of the numerous animal captures, there appears to be no reproductive compromise associated with this observation. The absence of sperm in adult male rats may be a result of a phenomenon known as azoospermia that may have a biological or genetic basis unrelated to chemical contamination at LHAAP (Tannenbaum, in preparation).

Min	1.00E+01	1.40E-01	5.85E-03
Max	1.00E+01	1.67E+01	3.40E+01
Arithmetic Mean	5.00E+00	8.40E+00	1.33E+01

Notes:

[a] Ratios were calculated by dividing the detected concentration in tissue by the detected concentration in surface soil (0-0.5 feet).

--- = Ratios were not calculated for a sample location if the chemical was not detected in both the tissue and soil media.

Shaded cells were non-detect for concentrations of the COPEC in plant tissue. BAFs were calculated using 1/2 the method detection limit in tissue.

BAF = Bioaccumulation factor

BERA = Baseline ecological risk assessment

COPEC = Chemical of potential ecological concern

Table 14-8
Results of Regression Analysis for Soil-to-Plant BAFs

Final Soil COPEC	N	B0 (intercept)	B1 (slope)	R^2	P model fit	Use for BERA? [a]
Barium	10	3.476	0.073	0.011	0.774	No
Cadmium	NA - No further refinement of the soil-to-plant pathway necessary for this COPEC					
Chromium	NA - No further refinement of the soil-to-plant pathway necessary for this COPEC					
Lead	NA - No further refinement of the soil-to-plant pathway necessary for this COPEC					
Zinc	NA - No further refinement of the soil-to-plant pathway necessary for this COPEC					
Perchlorate	NA - Due to the number of non-detects, data set not sufficiently robust for regression analysis (see text for details)					
2,4-DNT	NA - Due to the number of non-detects, data set not sufficiently robust for regression analysis (see Table 14-7)					
2,6-DNT	NA - Due to the number of non-detects, data set not sufficiently robust for regression analysis (see Table 14-7)					
2,4,6-TNT	NA - Due to the number of non-detects, data set not sufficiently robust for regression analysis (see Table 14-7)					

Notes:

Model: ln(plant) = B0 + B1 (ln[soil])

[a] Regression equation is used as the BAF for the BERA if the model slope (P Model Fit) is significantly different from zero ($p<0.05$), and the coefficient of determination (R^2) reflects a significant regression equation. The criterion for significance with sample size (n) of 10 is 0.399 (Steel, R.G.D. and J.H. Torrie, 1980, Principles and Procedures of Statistics, A Biometrical Approach, 2nd Edition, McGraw-Hill Book Company, New York.)

BAF = Bioaccumulation factor

BERA = Baseline ecological risk assessment

COPEC = Chemical of potential ecological concern

NA = Not applicable

Table 14-9

Ratios [a] Used for the Development of Sediment-to-Benthic Invertebrate Uptake Factors for Metals

BERA Sample Location	Sediment-to-Benthic Invertebrate BAFs for Final COPECs			
	Lead	Mercury	Silver	Thallium
CL-GPSN-2	2.88E-01	1.00E-01	NA [b]	NA [c]
CL-GPSN-3	4.89E-01	4.34E-01		
CL-GPSN-4	8.90E-01	2.95E-01		
CL-GPSS-2	6.84E-02	2.80E-01		
CL-GPSS-3	3.01E-01	2.17E-01		
GPWSD02	3.64E-01	1.33E+00		
GPWSD03	1.00E-01	1.69E+00		
IWSD06	1.32E-01	1.67E+00		
Min	6.84E-02	1.00E-01		
Max	8.90E-01	1.69E+00		
Arithmetic Mean	3.29E-01	7.52E-01		

Notes:

[a] Ratios were calculated by dividing the detected concentration in tissue by the detected concentration in sediment.

[b] No further refinement of the sediment-to-benthic invertebrates pathway necessary for this COPEC.

[c] All *Lumbriculus* tissue samples were non-detect for thallium. The method detection limit (MDL) was several orders of magnitude greater than the low (typically "J"-flagged") concentrations in sediment due to low percent solids in the samples. Therefore, uptake factor ratios based on 1/2 the MDL are artificially high, and were not used to calculate an average BAF ratio.

BAF = Bioaccumulation factor
BERA = Baseline ecological risk assessment
COPEC = Chemical of potential ecological concern
NA = Not applicable

Table 14-10
Results of Regression Analysis for Sediment-to-Benthic Invertebrate BAFs

Final Sediment COPEC	N	B0 (intercept)	B1 (slope)	R^2	P model fit	Use for BERA? [a]
Lead	8	-3.014	1.373	0.826	0.002	Yes
Mercury	8	-1.572	0.089	0.046	0.610	No
Silver	NA - No further refinement of the sediment-to-aquatic invertebrates pathway necessary for this COPEC					
Thallium	NA - Due to the number of non-detects, data set not sufficiently robust for regression analysis (see Table 14-9)					

Notes:

Model: ln(aq inv) = B0 + B1 (ln[sediment])

[a] Regression equation is used as the BAF for the BERA if the model slope (P Model Fit) is significantly different from zero ($p<0.05$), and the coefficient of determination (R^2) reflects a significant regression equation. The criterion for significance with sample size (n) of 8 is 0.500 (Steel, R.G.D. and J.H. Torrie, 1980, Principles and Procedures of Statistics, A Biometrical Approach, 2nd Edition, McGraw-Hill Book Company, New York.)

BAF = Bioaccumulation factor

BERA = Baseline ecological risk assessment

COPEC = Chemical of potential ecological concern

NA = Not applicable

Table 14-11
Selection of Final Soil-to-Earthworm Bioaccumulation Factors for Soil COPECs

Final Soil COPEC	Previous Tier 1 BAF [a]	Calculated BERA BAF Ratio	Regression Equation Based on Data from BERA	BAF Selected for BERA	Rationale
Barium	0.16	0.025	$\ln(C_e) = 0.624 * \ln(C_s) - 1.923$	BERA regression eq.	Regression equation based on field data most appropriate
Cadmium	25.25	6.10	$\ln(C_e) = 0.36 * \ln(C_s) + 0.42$	BERA regression eq.	Regression equation based on field data most appropriate
Chromium	3.162	0.019	Not Significant	0.019	BAF based on field data most appropriate
Lead	0.36	0.022	$\ln(C_e) = 1.01 * \ln(C_s) - 4.041$	BERA regression eq.	Regression equation based on field data most appropriate
Zinc	4.65	0.48	Not Significant	0.48	BAF based on field data most appropriate
Perchlorate	1.14	Soil-to-earthworm pathway did not require further evaluation in the BERA			
2,4-DNT	13.43	0.064 b	NA	0.064	BAF based on field data most appropriate
2,6-DNT	13.43	0.35 b	NA	0.35	BAF based on field data most appropriate
TNT	13.3	0.36 b	NA	0.36	BAF based on field data most appropriate

Notes:

[a] See Table 7-21 in Volume I of the BERA. Note that BAFs based on regression equations (i.e., cadmium, lead, and zinc) that are concentration-dependent were estimated using the 0-0.5 foot exposure point concentration for the chemical in the Industrial Sub-Area.

[b] Seven out of eight BAF soil/tissue explosives ratios were non-detect for 2,4-DNT, 2,6-DNT, and TNT in earthworm tissue; however, the reporting limits were not elevated in relation to soil concentrations and could be used to estimate tissue concentrations at 1/2 the method detection limit.

BAF = Bioaccumulation factor

BERA = Baseline ecological risk assessment

C_e = Concentration in earthworm

C_s = Concentration in soil

COPEC = Chemical of potential ecological concern

NA = Not applicable; BERA data were not robust enough for regression analysis.

Table 14-12
Selection of Final Soil-to-Plant Bioaccumulation Factors for Soil COPECs

Final Soil COPEC	Previous Tier 1 BAF [a]	Calculated BERA BAF Ratio	Regression Equation Based on Data from BERA	BAF Selected for BERA	Rationale
Barium	0.92	0.73	Not Significant	0.73	BAF based on field data most appropriate
Cadmium	0.93	Soil-to-plant pathway did not require further evaluation in the BERA			
Chromium	0.48	Soil-to-plant pathway did not require further evaluation in the BERA			
Lead	0.1	Soil-to-plant pathway did not require further evaluation in the BERA			
Zinc	0.72	Soil-to-plant pathway did not require further evaluation in the BERA			
Perchlorate	6.57	14,318 (4.8) b, c	NA	Tier 1 regression eq. [e]	BERA BAF not appropriate to use; see footnotes b and c
2,4-DNT	2.78	5.0 d	NA	2.78	BERA BAFs artificially high due to elevated detection limits; use Tier 1 value
2,6-DNT	2.37	8.4 d	NA	2.37	BERA BAFs artificially high due to elevated detection limits; use Tier 1 value
TNT	0.32	13.3 d	NA	0.32	BERA BAFs artificially high due to elevated detection limits; use Tier 1 value

Notes:

[a] See Table 7-20 in Volume I of the BERA. Note that BAFs based on regression equations (i.e., cadmium, lead, zinc, and perchlorate) that are concentration-dependent were estimated using the 0.0-5 foot exposure point concentration for the chemical in the Industrial Sub-Area.

[b] The BERA BAF was calculated by dividing the single detected plant concentration of 189 mg/kg by the co-located shallow (0-0.5 foot) BERA surface soil concentration (0.0132 mg/kg). The value in parentheses is the BAF that is calculated using the perchlorate concentration from the historical dataset (i.e., 39 mg/kg) that was detected in that sample location at a deeper soil depth (1-2 feet sample interval).

[c] BAF is based on a single detection of perchlorate in tissue and soil. The plant (tree) that was sampled is more likely to be associated with deeper soil than the 0-0.5 foot BERA sample. Using soil concentrations in the historical dataset from a deeper (1-2 feet) soil interval resulted in a BAF (i.e., 4.8) similar to that calculated by the Sample et al. regression equation (i.e., 6.57). Therefore, the regression equation is considered to be a more appropriate reflection of soil-plant uptake for perchlorate rather than the BERA BAF ratio that is based on a single shallow surface soil sample.

[d] Seven out of eight BAF soil/tissue explosives ratios were non-detect in plant tissue. Detection limits for plant tissue were greatly elevated in relation to soil concentrations.

[e] Regression equation: ln (BAF) = 0.5891(ln[soil])+2.41. See Sample, B.E, A. Tsao, and M.S. Johnson, 2005, *Development of Soil-to-Plant Bioaccumulation Models for Energetic Compounds and Metabolites* , presentation at the 2005 Society of Environmental Toxicology and Chemistry (SETAC) conference, Baltimore, MD. (using the equation for pooled monocots and dicots.)

BAF = Bioaccumulation factor

BERA = Baseline ecological risk assessment

C_p = Concentration in plant

C_s = Concentration in soil

COPEC = Chemical of potential ecological concern

NA = Not applicable; BERA data were not robust enough for regression analysis.

Table 14-13
Selection of Final Sediment-to-Benthic Invertebrate Bioaccumulation Factors for Sediment COPECs

Final Sediment COPEC	Previous Tier 1 BAF [a]	Calculated BERA BAF Ratio	Regression Equation Based on Data from BERA	BAF Selected for BERA	Rationale
Lead	0.607	0.33	$\ln(C_{inv}) = 1.373 * \ln(C_{sed}) - 3.014$	BERA regression eq.	Regression equation based on field data most appropriate
Mercury	2.868	0.75	Not Significant	0.75	BAF based on field data most appropriate
Silver	4.5	NA - No further refinement of the sediment-to-benthtic invertebrates pathway necessary for this COPEC			
Thallium	4.5	NA [c]		4.5	BERA BAFs artificially high due to elevated detection limits; use Tier 1 value

Notes:

[a] See Table 7-23 in Volume I of the BERA.

[b] Silver was only selected as a final COPEC due to concerns regarding direct contact toxicity; no site-specific BERA sediment-benthic invertebrate BAFs were calculated.

[c] All eight *Lumbriculus* tissue samples were non-detect for thallium. Method detection limits for tissue were greatly elevated in relation to estimated (J-qualified) sediment concentrations, and would have resulted in inappropriately high BAFs. Therefore, no BAFs were calculated for thallium based on the BERA data.

BAF = Bioaccumulation factor

BERA = Baseline ecological risk assessment

C_{inv} = Concentration in invertebrate

C_{sed} = Concentration in sediment

COPEC = Chemical of potential ecological concern

NA = Not applicable

15.0 Step 7: Risk Characterization

Section 15.0 presents Step 7, the results of the risk characterization.

15.1 Refined Food Chain Modeling Results Using Site-Specific Data

The food chain models that were used to estimate hazard for the selected measurement receptors at LHAAP in the BERA were the same models presented in the SLERA (**Section 7.2**, **Volume I**); however, they were re-run using the site-specific data presented in **Section 14**. The following changes in the food chain models for the BERA were applied to estimate hazard associated with the Final COPECs:

- Separate analyses for mammals were performed for Cr^{III} and Cr^{VI} using the site-specific Cr speciation data collected during the BERA. The EPCs for Cr^{III} and Cr^{VI} were calculated as the EPC for total Cr multiplied by 0.986 and 0.014, respectively, based on the 70:1 Cr^{III} to Cr^{VI} site-specific ratio determined to be present at LHAAP (see **Section 14.1**). Because only a TRV for Cr^{III} is available for birds, it was not necessary to calculate separate EPCs for avian receptors, and all Cr modeled for avian exposure was assumed to be Cr^{III}.

- The site-specific BAFs described in **Section 14.2** (**Tables 14-11** through **14-13)** were used in place of literature values, as appropriate.

- The lead EPCs in total and surface soil for the Waste Sub-Area were modified to include the concentrations identified in the Pistol Range data that were collected in 2006 (see **Section 10.1.6.2, Volume I**). Pistol Range samples were analyzed using both laboratory and XRF screening techniques. XRF data are generally not considered to be of sufficient quality for risk assessment purposes. Therefore, only the laboratory data were included in the re-calculation of the soil EPCs. (It is noted that a 95 percent UCL EPC using the lead dataset with the XRF data included is actually lower than when it is omitted.) The revised lead EPCs were considerably greater than those calculated without the Pistol Range data (previous Waste Sub-Area EPC for lead in surface soil and total soil was 74.4 and 55.9 mg/kg, respectively; the new EPCs were 178 and 151 mg/kg, respectively).

The eight food chain models for the various sub-area and watershed combinations were re-run incorporating the above changes, and EEQs associated with the final COPECs were calculated for all measurement receptors. The results of these models are summarized in **Tables 15-1** through **15-8**. These summary tables present the NOAEL- and LOAEL-based EEQs for the BERA food chain model iterations for each receptor for those chemicals that were identified as a final COPEC in the particular sub-area and/or watershed. For example, **Table 15-1**, which presents the summary for the Industrial Sub-Area and Goose Prairie Creek food chain model, includes EEQs associated with the soil final COPECs identified in the Industrial Sub-Area

(cadmium, Cr, zinc, and perchlorate) as well as the sediment final COPECs for Goose Prairie Creek (lead, mercury, silver, and thallium). The food chain model summary for the Low Impact Sub-Area/Saunders Branch watershed (**Table 15-6**) does not present any EEQs because there were no final COPECs in that sub-area or watershed. The BERA food chain models were run using the Tier 1 assumptions described in **Volume I**, **Section 7.2**, except as noted above. The Tier 2 results are not provided in the tables, as stakeholders have stated that risk decisions will not be made based on these data. In the tables, EEQs greater than 1 are shaded and bolded. Only receptors that had at least one EEQ greater than 1 are shown. The complete food chain model spreadsheets are presented in **Appendix O**.

Because hazard is assessed across all media and pathways, it is necessary to determine the medium-specific hazard for each final COPEC so that it can be determined which final COPECs, by medium, require further discussion and/or action in the risk management step (i.e., Step 8). A summary of the specific hazards associated with only the medium of concern (i.e., soil or sediment) for each of the final COPECs is presented in **Tables 15-9** and **15-10**. These tables isolate the medium-specific NOAEL- and LOAEL-based EEQs for the receptors that exceeded an EEQ of 1 from the previous food chain analysis (**Volume I**), and that were targeted for further refinement in the BERA (see **Tables 11-1** and **11-2**). The following Final COPECs had NOAEL EEQs that exceeded 1 for one or more receptors after the BERA site-specific data were applied to the food chain models:

SOIL (**Table 15-9**):

- Barium (Waste Sub-Area)
- Lead (Waste Sub-Area)
- 2,4-DNT (Waste Sub-Area)
- 2,6-DNT (Waste Sub-Area)
- 2,4,6-TNT (Waste Sub-Area)
- Dioxin (Waste Sub-Area)

SEDIMENT (**Table 15-10**):

- Mercury (Goose Prairie Creek)
- Thallium (Goose Prairie Creek, Harrison Bayou, and Central Creek)

These chemicals are carried forward for PRG development (**Section 15.7**).

15.2 Sediment Toxicity Test Results

Based on the evaluation of sediment toxicity using site-specific test results (**Section 14.2.5**), elevated concentrations of lead in the north Goose Prairie Creek Cove area of Caddo Lake appear to be related to statistically significant ($p < 0.05$) aquatic toxicity. The maximum

detected sediment lead concentration of 352 mg/kg was associated with a 40 percent reduction in amphipod survival. In addition, the two highest sediment lead concentrations (352 and 246 mg/kg, respectively) were both associated with amphipod growth reductions of 37.5 percent. The sample with the third highest sediment lead concentration (191 mg/kg) was not statistically different for either survival or growth from the lake reference sample. Therefore, based on the results of these site-specific toxicity tests, the NOAEL for lead in sediment is 191 mg/kg. Concentrations of the other two sediment COPECs (mercury and silver) do not appear to be related to the observed amphipod toxicity, based on visual comparisons of concentration and toxicity trends among the sample results (**Figures 14-4** and **14-5**).

Sediment samples collected from Goose Prairie Creek watershed (**Section 14.2.5**) were not statistically different for either survival or growth from the stream reference sample. Therefore, it is concluded that none of the final COPECs in sediment in the Goose Prairie Creek watershed are present at sufficiently high concentrations to pose significant toxicity to aquatic organisms, based on the BERA field data.

15.3 Direct Contact Soil Toxicity Evaluation

Results of the direct contact soil toxicity evaluation based on benchmark comparisons performed as part of the Step 3 evaluation (**Section 7.1.1, Volume I**) are summarized here. This summary is provided for purposes of transparency as requested by stakeholders. Based on previous agreements between the Army and the stakeholders, no soils at LHAAP will be remediated to protect receptors at the base-of-the-food-chain (i.e., terrestrial plants and terrestrial invertebrates).

The only changes in the benchmark screen from the Step 3 evaluation are as follows:

- The incorporation of site-specific Cr speciation results (i.e., Cr^{VI} is 1.4 percent of total Cr; **Section 14.1**) alters findings for potential Cr toxicity to terrestrial plant and invertebrate receptors. During Step 3, it was speculated that most of the Cr in soil was the less toxic form of Cr (i.e., Cr^{III}). This was confirmed by field studies. All sub-areas exceeded the Cr^{VI} earthworm benchmark, and both the Cr^{VI} and Cr^{III} plant benchmarks. Because only the Cr^{VI} benchmark was exceeded for terrestrial invertebrates, chromium is of low concern for these organisms due to the limited Cr^{VI} determined to be present in Installation soils. However, there is still some concern regarding toxicity to plants from Cr^{III}.
- The incorporation of a revised lead EPC for total soil at the Waste Sub-Area based on the addition of Pistol Range data collected in 2006 (**Section 15.1**)
- The presentation of terrestrial invertebrate (earthworm) survival results that were recorded during the soil-to-invertebrate bioaccumulation study (Section 3.3 in **Appendix N**)

During Step 3, EEQs were generated for each preliminary COPEC detected in soil. The EEQ is the EPC of a final COPEC in soil divided by the appropriate plant or invertebrate benchmarks. EEQs greater than 1 indicate an exceedance of the benchmark, and the potential for toxic effects. Two tiers of direct toxicity screens were conducted for both earthworms and plants. The Tier 1 screen used the 95 percent UCL concentration of each final COPEC in soil as the EPC, while the Tier 2 screen used the mean soil concentration as the EPC. The following subsections describe the direct contact soil toxicity evaluations for each area of concern.

15.3.1 Industrial Sub-Area

Of the chemicals for which an earthworm benchmark was available, Cr and mercury had EEQs that exceeded 1 for both the Tier 1 and Tier 2 screens (**Volume I**, **Table 7-1**). The hexavalent Cr EEQ dropped to 0.6 when the soil concentration was adjusted to account for the measured Cr speciation at LHAAP (**Section 14.1**). It should also be noted that earthworm survival during the 28-day bioaccumulation study averaged 98.3 percent for the five soil samples collected at this sub-area (**Appendix N**). This finding supports the conclusion that soil invertebrates are not being adversely affected by COPECs in LHAAP soils.

For the plant direct toxicity analysis, aluminum (both Tiers), Cr (both trivalent and hexavalent; both Tiers), mercury (Tier 1 only), selenium (both Tiers), vanadium (both Tiers) and zinc (both Tiers) exceeded benchmarks (**Volume I**, **Table 7-2**). The hexavalent Cr plant EEQ dropped to 0.7 when the soil concentration was adjusted to account for the measured Cr speciation at LHAAP (**Section 14.1**). Although a formal vegetation survey was not conducted at LHAAP during the BERA, no areas of stressed vegetation were observed in the Industrial Sub-Area during field work or other site visits.

15.3.2 Low Impact Sub-Area

Of the chemicals for which an earthworm benchmark was available, only Cr had an EEQ that exceeded 1 (**Volume I**, **Table 7-3**). The hexavalent Cr EEQ dropped to 0.4 when the soil concentration was adjusted to account for the measured Cr speciation at LHAAP (**Section 14.1**). For the plant direct toxicity evaluation, Cr (both trivalent and hexavalent; both Tiers), manganese (both Tiers), vanadium (both Tiers), and zinc (Tier 1 only) exceeded benchmarks (**Volume I**, **Table 7-4**). The hexavalent Cr plant EEQ dropped to 0.5 (Tier 1) and 0.4 (Tier 2) when the soil concentration was adjusted to account for the measured Cr speciation at LHAAP (**Section 14.1**). Although a formal vegetation survey was not conducted at LHAAP during the BERA, no areas of stressed vegetation were observed in the Low-Impact Sub-Area during field work or other site visits.

15.3.3 Waste Sub-Area

Of the chemicals for which an earthworm benchmark was available, barium, Cr, and 2,4,6-TNT had EEQs that exceeded 1 for both Tiers (**Volume I**, **Table 7-5**). The hexavalent Cr EEQ dropped to 0.6 when the soil concentration was adjusted to account for the measured Cr speciation at LHAAP (**Section 14.1**). It should also be noted that earthworm survival during the 28-day bioaccumulation study averaged 98.0 percent for the five soil samples collected at this sub-area (**Appendix N**). This finding supports the conclusion that soil invertebrates are not being adversely affected by COPECs in LHAAP soils.

For the plant direct toxicity analysis, aluminum (both tiers), barium (Tier 1 only), Cr (both trivalent and hexavalent; both tiers), lead (Tier 1 only), vanadium (both tiers), zinc (Tier 1 only), and 2,4,6-TNT (both tiers) exceeded benchmarks (**Volume I**, **Table 7-6**). The hexavalent Cr plant EEQ dropped to 0.7 (Tier 1) and 0.6 (Tier 2) when the soil concentration was adjusted to account for the measured Cr speciation at LHAAP (**Section 14.1**). Although a formal vegetation survey was not conducted at LHAAP during the BERA, no areas of stressed vegetation were observed in the Waste Sub-Area during field work or other site visits.

When the revised lead EPC in the Waste Sub-Area is used to account for incorporation of the 2006 Pistol Range data, the earthworm EEQ increased from 0.11 to 0.30 (Tier 1) and from 0.09 to 0.24 (Tier 2). The plant EEQ, using the revised Waste Sub-Area lead EPC, increased from 1.1 to 3.0 (Tier 1) and from 0.9 to 2.4 (Tier 2).

15.4 RSA Results

For the hispid cotton rat (the dominant rodent species caught at LHAAP during the RSA Study), none of the established sperm parameter thresholds for effect were exceeded at the three study sites (**Appendix P**). The results are interpreted to mean that reproductive capability is not compromised in maximally exposed terrestrial receptors (small rodents) and, by extension, in other larger and wider-ranging mammals. Corroboration for this finding is provided by the similarity in total animal captures at the study sites and the reference areas. Although some hispid cotton rats at the Plant 2 area were observed to have no sperm, there appears to be no population-level reproductive compromise associated with this observation given the numerous animal captures (**Section 14.3**).

15.4.1 RSA Findings and LHAAP Chemical Concentrations in Soil

Chemical analytical results for near surface soil samples (generally with the 0 to 2 foot range) collected at LHAAP at or near the three RSA study areas (the Plant 2 Area, the associated Plant 2 Wetlands Area, and the Goose Prairie Creek Drainage Area) were compiled to estimate the chemical exposure conditions for the small rodents evaluated in the RSA Study. It should be noted that reviewing chemical analytical results for soil is not part of the RSA method; however,

chemical analytical results for soil were reviewed during the BERA to establish a relationship between RSA results and concentrations of chemicals detected in soil at LHAAP. A list of samples included in this evaluation is provided in **Table 15-11**. Soil and dry sediment sample results were used in the data compilation if they were collected within 500 feet of a RSA rodent capture location. The home range of a hispid rat cotton rat is approximately 1.25 acres (Hawthorne, 1994), and the 500 foot distance was considered to be representative of the RSA capture locations.

Based on the soil sample analytical data, summary statistics and 95 percent UCL EPCs were determined for the final soil COPECs, as well as for two background inorganic chemicals (aluminum and vanadium) following the procedures employed in **Volume I**, **Section 6.1.3.3**. Soil concentration results are presented in **Table 15-12**. 95 percent UCL soil concentrations are representative of the exposure conditions experienced by the hispid cotton rats. Because rodents were determined not to be adversely affected based on the results of the RSA study, these site-specific chemical concentrations (95 percent UCLs) may be considered as NOAEL soil concentrations for the reproductive endpoint in small mammals. For the three RSA study areas, the 95 percent UCLs are summarized as follows:

Soil COPEC	Plant 2 Area 95% UCL (mg/kg)	Wetland Area 95% UCL (mg/kg)	GPC Drainage Area 95% UCL (mg/kg)	Highest 95% UCL (mg/kg)
Barium	300	171	115	300
Cadmium	2.14	0.57	0.269	2.14
Chromium (total)	27	15.2	35.3	35.3
Lead	36.2	14.3	19.1	36.2
Zinc	127	132	56.4	132
2,4-DNT	NA	0.0328	0.0342	0.0342
2,6-DNT	NA	0.0328	0.0342	0.0342
2,4,6-TNT	NA	NA	NA	NA
Perchlorate	0.0486	NA	NA	0.0486
2,3,7,8-TCDD TEQ	7.58E-06	NA	NA	7.58E-06
Background Inorganic Chemicals				
Aluminum	8,800	10,646	7,760	10,646
Vanadium	47.2	21.1	53.1	53.1

The highest 95 percent UCLs for a given chemical, which were generally found in the Plant 2 Area, are recommended for use as NOAEL soil concentrations associated with the RSA, and are considered further in **Section 15.5** and following sections. Aluminum and vanadium are not discussed further in **Section 15.5**, as they are background related.

15.5 Weight of Evidence Discussion

This weight of evidence discussion includes the primary lines of evidence presented and discussed in the BERA including:

- Refined food chain modeling findings using site-specific data
- Sediment toxicity test findings (along with AVS-SEM results)
- RSA findings (including small mammal densities measured in the field)

Each of these lines of evidence has its own strengths and weaknesses. The refined food chain modeling results are very relevant as they use site-specific BAFs and Cr speciation data, but they still represent a modeling approach that may not accurately predict actual population effects in the environment at LHAAP. Additionally, the food web models used in this BERA retain a certain level of conservatism and the estimated wildlife EEQs likely overestimate, rather than underestimate, actual ecological hazards for the receptors evaluated (**Section 15.1**).

The sediment toxicity test results present site-specific data and appear to identify lead as the major toxicant in several sediment samples collected from the north cove of Goose Prairie Creek Cove in Caddo Lake. These laboratory results may over- or underestimate in situ sediment toxicity based on the fact that the sediment samples went through extensive handling and disturbance prior to toxicity testing. However, the fact that AVS were not detected in the sediment samples (likely due to desiccated sediment resulting from drought conditions present prior to, and during, the sampling event) strongly suggests that toxicity was overestimated in the toxicity tests compared with normal in situ conditions (**Section 15.2**). In general, site-specific toxicity test results are much more useful for risk assessment purposes compared with the use of generic default sediment benchmarks. However, using re-hydrated dry sediments for the toxicity tests introduces additional uncertainty regarding how well the toxicity results reflect actual or potential toxicity during normal (i.e., non-drought) conditions.

The RSA results are most relevant for the purposes of assessing actual hazard to current small mammal populations at LHAAP exposed to COPECs in soil (**Section 15.3**). Although other wildlife receptors (such as birds) are not directly addressed by the RSA technique, it is reasonable to assume that small mammals are more closely associated with soil than other receptors and, therefore, serve as worst-case surrogates for other, less exposed wildlife expected at LHAAP. The results of the RSA study are somewhat limited because of the fact that only the Industrial Sub-Area and associated Goose Prairie Creek watershed were used as study areas; however, estimated NOAEL COPEC soil concentrations derived from these areas are directly applicable to the other areas of LHAAP (e.g., the Waste and Low-Impact Sub-Areas). A potential concern that arose from the RSA study is that some of the hispid cotton rats captured in the Plant 2 area were found to be azoospermic; however, this condition may have a biological or genetic basis unrelated to chemical contamination at LHAAP (**Section 14.3.3** and **Appendix P**).

The RSA results also address the phenomenon of chemical mixtures. In other words, because the rodents being studied are in direct contact with the soil (and all chemicals therein), it can be stated that the sum total of COPEC stressors at the Industrial Sub-Area are not impacting reproduction of these maximally-exposed small mammal receptors. In addition, RSA results also provide a line of evidence for avifauna not being impacted because bird exposure to soil is generally much less than rodents. Birds do not contact the ground nearly as much as small rodents, and birds are migratory species whereas mammals have a very small home range that creates a tight spatial relationship with the terrestrial system. When this information is considered, along with the observation that, for many COPECs, mammals have lower thresholds for effect (i.e., lower NOAEL- and LOAEL-based TRVs) than do birds, RSA outcomes can be used to strongly suggest that site birds are also probably not adversely impacted by chemical stressors.

Regardless of potential impacts from exposure to chemicals in site media, results of small mammal densities documented at the study areas and the paired reference locations indicated that there were no apparent impacts to small mammal populations at LHAAP.

15.6 Additional Risk Information

Additional risk information, which should be considered concurrently with an assessment of potential ecological hazard at LHAAP, is presented and discussed in this section.

A number of COPECs were determined to be background-related during the Step 3 evaluation (**Section 10.4**) and not formally evaluated in the BERA. These background COPECs were summarized in **Table 10-1** (**Volume I**) and are presented in the table below, along with their estimated EEQs that were calculated using the EPC (typically, the 95 percent UCL) from that particular sub-area or watershed. The maximum NOAEL-based EEQ of any receptor associated with the background chemical and the medium is also presented, with the receptor abbreviation listed in parentheses (i.e., STS = Short-tailed Shrew, RAC = Raccoon, RO = River Otter). It should be noted that these EEQs are based on the conservative assumptions used in the Step 3 food chain model (see **Volume I**) because they were not targeted for additional characterization in the BERA. Therefore, they are likely to overestimate potential hazard associated with background chemicals and many EEQs are unrealistically high and toxicologically implausible (Tannenbaum, 2002; 2003a; 2005). The notation "All < 1" indicates that the chemical did not exceed an EEQ of 1 for any receptor, but was placed on the background list due to concerns related to direct contact toxicity. Blank cells in the table indicate the COPEC was not selected as a final COPEC (see **Section 10.5**, **Volume I**, for details).

COPEC	Soil			Sediment				Surface Water			
	ISA	WSA	LISA	GPC	CC	HB	SB	GPC	CC	HB	SB

These background COPECs detected on the Installation may exert some additional hazard on receptors at LHAAP, in addition to the hazards associated with the selected final COPECs. However, this additional hazard is expected to be minor, as the receptors have been exposed to these background COPECs for many generations and are likely unaffected by their presence. The fact that a variety of species currently live on and use habitat at the Installation suggests that they are tolerant of hazard associated with background concentrations, although it is possible that less tolerant species have been displaced. One or more of the following points also apply to the chemicals presented in this list of background COPECs:

- The spatial organization of detected concentrations of these background COPECs does not suggest a hot spot. For example, some chemicals, such as thallium, were only detected sporadically at very low concentrations. For other chemicals, no concentration gradient from a potential source area was identified;
- Many of these background COPECs had a TRV effect that was not critical;
- Many of these background COPECs were not considered to be direct contact hazards (**Table 10-2** through **10-4**).

Therefore, no further consideration of these background COPECs is recommended.

15.7 Estimation of Food Web-Based Ecological PRGs

15.7.1 Soil

COPEC NOAEL concentrations estimated using RSA results, and soil sample analytical results collected during investigative activities at the Installation, were presented in **Section 15.4.1**, and represent values that may be used for NOAEL-based ecological preliminary remediation goals (EcoPRG). COPEC NOAEL and LOAEL concentrations estimated using the refined food chain models can be estimated using EPCs and EEQs from the refined food chain model (**Appendix O** and **Table 15-9**). As discussed in **Section 15.1**, there are five final COPECs in the Waste Sub-Area that require the calculation of food web-based EcoPRGs: barium, lead, 2,4-DNT, 2,6-DNT, 2,4,6-TNT, and Dioxin. These calculations are presented in the following subsections. Due to stakeholder concerns regarding a number of uncertainties involved with the RSA study (e.g., low sample size, variability in response, sample design, etc.), the RSA results are not used to calculate the primary EcoPRGs recommended in this BERA. However, the RSA study does present data on real-world observations of a class of organisms intimately associated with the soil in the most contaminated parts of the Installation, and the results have some value. Therefore, for certain chemicals "secondary EcoPRGs" are presented based on results of the RSA study. These secondary EcoPRGs may be considered as secondary cleanup values provided to risk managers that could be considered during an FS, along with other factors when final cleanup goals are selected.

Barium. As four receptors had EEQs above 1 (**Table 15-9**), separate food web-based EcoPRGs are necessary for each receptor, except as noted below for the Townsend's Big-Eared Bat.

- Townsend's Big-Eared Bat: As this receptor is a surrogate for a listed threatened or endangered species (the Rafinesque's big-eared bat), EcoPRGs may only be calculated based on the NOAEL (per TNRCC, 2001). Given a surface soil EPC of 1,011 mg/kg for barium and a NOAEL-based EEQ of 4.02, the NOAEL-based EcoPRG is 1011/4.02, or 252 mg/kg.
- Raccoon: Given a surface soil EPC of 1,011 mg/kg and a NOAEL-EEQ of 4.86, the NOAEL-based EcoPRG is 208 mg/kg. Given a surface soil EPC of 1,011 mg/kg and a LOAEL-EEQ of 1.25, the LOAEL-based EcoPRG is 808 mg/kg.
- Deer Mouse: Given a surface soil EPC of 1,011 mg/kg and a NOAEL-EEQ of 7.18, the NOAEL-based EcoPRG is 141 mg/kg. Given a surface soil EPC of 1,011 mg/kg and a LOAEL-EEQ of 1.85, the LOAEL-based EcoPRG is 547 mg/kg.
- Short-Tailed Shrew: Given a total soil EPC of 553 mg/kg and a NOAEL-EEQ of 1.67, the NOAEL-based EcoPRG is 331 mg/kg. Given a total soil EPC of 553 mg/kg and a LOAEL-EEQ of 0.431, the LOAEL-based EcoPRG is 1,283 mg/kg.

Lead. As only the American Woodcock had an EEQ above 1 (**Table 15-9**), food web-based EcoPRGs are necessary for this receptor only.

- American Woodcock: Given a surface soil EPC of 178 mg/kg and a NOAEL-EEQ of 2.38, the NOAEL-based EcoPRG is 75 mg/kg. Given a surface soil EPC of 178 mg/kg and a LOAEL-EEQ of 0.238, the LOAEL-based EcoPRG is 748 mg/kg. However, as discussed in **Section 10.1.6.1**, the lead TRVs used for the estimation of these EEQs were based on lead acetate in the laboratory toxicity study, not metallic lead. The lead acetate NOAELs and LOAELs were 1.13 mg/kg-day and 11.3 mg/kg-day, respectively (**Table 7-25** in **Volume I**). As lead acetate is not expected to be present in the environment at LHAAP and metallic lead is less bioavailable than lead acetate, the alternative metallic lead TRVs (i.e., NOAEL = 3.85 mg/kg-day and LOAEL = 11.55 mg/kg-day [Pattee, 1984 in Sample et al., 1996], **Table 7-25**) are recommended for use. The application of these alternative metallic lead TRVs results in an increase of the NOAEL-based EcoPRG by a factor of 3.4 (i.e., 3.85/1.13 mg/kg-day), and an increase in the LOAEL-EcoPRG by a factor of 1.02 (i.e., 11.55/11.3 mg/kg-day). Therefore, the recommended NOAEL- and LOAEL-based EcoPRGs are 255 and 763, respectively.

2,4-DNT. As two receptors had EEQs above 1 (**Table 15-9**), separate food web-based EcoPRGs are necessary for each receptor.

- Short-Tailed Shrew: Given a total soil EPC of 101 mg/kg and a NOAEL-EEQ of 10.5, the NOAEL-based EcoPRG is 9.6 mg/kg. Given a total soil EPC of 101 mg/kg and a LOAEL-EEQ of 1.4, the LOAEL-based EcoPRG is 72 mg/kg.
- Red Fox: Given a total soil EPC of 101 mg/kg and a NOAEL-EEQ of 22.9, the NOAEL-based EcoPRG is 4.4 mg/kg. Given a total soil EPC of 101 mg/kg and a LOAEL-EEQ of 3.05, the LOAEL-based EcoPRG is 33 mg/kg.

2,6-DNT. As three receptors had EEQs above 1 (**Table 15-9**), separate food web-based EcoPRGs are necessary for each receptor.

- Deer Mouse: Given a surface soil EPC of 2.4 mg/kg and a NOAEL-EEQ of 1.54, the NOAEL-based EcoPRG is 1.6 mg/kg. Given a surface soil EPC of 2.4 mg/kg and a LOAEL-EEQ of 0.512, the LOAEL-based EcoPRG is 4.7 mg/kg.
- Short-Tailed Shrew: Given a total soil EPC of 13.6 mg/kg and a NOAEL-EEQ of 3.51, the NOAEL-based EcoPRG is 3.9 mg/kg. Given a total soil EPC of 13.6 mg/kg and a LOAEL-EEQ of 1.17, the LOAEL-based EcoPRG is 12 mg/kg.
- Red Fox: Given a total soil EPC of 13.6 mg/kg and a NOAEL-EEQ of 2.99, the NOAEL-based EcoPRG is 4.5 mg/kg. Given a total soil EPC of 13.6 mg/kg and a LOAEL-EEQ of 0.998, the LOAEL-based EcoPRG is 14 mg/kg.

2,4,6-TNT. As eight receptors had EEQs above 1 (**Table 15-9**), separate food web-based EcoPRGs are necessary for each receptor, except as noted below for the Townsend's Big-Eared Bat and Raccoon (Louisiana Black Bear).

- Deer Mouse: Given a surface soil EPC of 491 mg/kg and a NOAEL-EEQ of 82, the NOAEL-based EcoPRG is 6.0 mg/kg. Given a surface soil EPC of 82 mg/kg and a LOAEL-EEQ of 54.6, the LOAEL-based EcoPRG is 9.0 mg/kg.
- Short-Tailed Shrew: Given a total soil EPC of 287 mg/kg and a NOAEL-EEQ of 75.5, the NOAEL-based EcoPRG is 3.8 mg/kg. Given a total soil EPC of 287 mg/kg and a LOAEL-EEQ of 50.3, the LOAEL-based EcoPRG is 5.7 mg/kg.
- Raccoon: Given a surface soil EPC of 491 mg/kg and a NOAEL-EEQ of 43.2, the NOAEL-based EcoPRG is 11 mg/kg. Given a surface soil EPC of 491 mg/kg and a LOAEL-EEQ of 28.8, the LOAEL-based EcoPRG is 17 mg/kg.
- Raccoon (Louisiana Black Bear): As this receptor is a surrogate for a listed threatened or endangered species (the Louisiana black bear), EcoPRGs may only be calculated based on the NOAEL, per TCEQ guidance (TNRCC, 2001). Given a surface soil EPC of 491 mg/kg for 2,4,6-TNT and a NOAEL-based EEQ of 5.58, the NOAEL-based EcoPRG is 88 mg/kg.
- Red Fox: Given a total soil EPC of 287 mg/kg and a NOAEL-EEQ of 51.2, the NOAEL-based EcoPRG is 5.6 mg/kg. Given a total soil EPC of 287 mg/kg and a LOAEL-EEQ of 34.1, the LOAEL-based EcoPRG is 8.4 mg/kg.
- Townsend's Big-Eared Bat: As this receptor is a surrogate for a listed threatened or endangered species (the Rafinesque's big-eared bat), EcoPRGs may only be calculated based on the NOAEL, per TCEQ guidance (TNRCC, 2001). Given a surface soil EPC of 491 mg/kg for 2,4,6-TNT and a NOAEL-based EEQ of 21.8, the NOAEL-based EcoPRG is 23 mg/kg.
- American Woodcock: Given a surface soil EPC of 491 mg/kg and a NOAEL-EEQ of 402, the NOAEL-based EcoPRG is 1.2 mg/kg. Given a surface soil EPC of 491 mg/kg and a LOAEL-EEQ of 15.6, the LOAEL-based EcoPRG is 31 mg/kg.
- Red-Tailed Hawk: Given a surface soil EPC of 491 mg/kg and a NOAEL-EEQ of 95.2, the NOAEL-based EcoPRG is 5.2 mg/kg. Given a surface soil EPC of 491 mg/kg and a LOAEL-EEQ of 3.7, the LOAEL-based EcoPRG is 133 mg/kg.

Dioxin. As five receptors had EEQs above 1 (**Table 15-9**), food web-based EcoPRGs are necessary for each receptor separately, except as noted below for the Raccoon (Louisiana Black Bear).

- Deer Mouse: Given a surface soil EPC of 7.33E-5 mg/kg and a NOAEL-EEQ of 75.7, the NOAEL-based EcoPRG is 9.7E-7 mg/kg. Given a surface soil EPC of

7.33E-5 mg/kg and a LOAEL-EEQ of 7.57, the LOAEL-based EcoPRG is 9.7E-6 mg/kg.

- Short-Tailed Shrew: Given a total soil EPC of 3.4E-5 mg/kg and a NOAEL-EEQ of 81.8, the NOAEL-based EcoPRG is 4.2E-7 mg/kg. Given a total soil EPC of 3.4E-5 mg/kg and a LOAEL-EEQ of 8.18, the LOAEL-based EcoPRG is 4.2E-6 mg/kg.

- Raccoon: Given a surface soil EPC of 7.33E-5 mg/kg and a NOAEL-EEQ of 12.5, the NOAEL-based EcoPRG is 5.9E-6 mg/kg. Given a surface soil EPC of 7.33E-5 mg/kg and a LOAEL-EEQ of 1.25, the LOAEL-based EcoPRG is 5.9E-5 mg/kg.

- Raccoon (Louisiana Black Bear): As this receptor is a surrogate for a listed threatened or endangered species (the Louisiana black bear), EcoPRGs may only be calculated based on the NOAEL, per TCEQ guidance (TNRCC, 2001). Given a surface soil EPC of 7.33E-5 mg/kg for dioxin and a NOAEL-based EEQ of 1.76, the NOAEL-based EcoPRG is 4.2E-5 mg/kg.

- American Woodcock: Given a surface soil EPC of 7.33E-5 mg/kg and a NOAEL-EEQ of 14.4, the NOAEL-based EcoPRG is 5.1E-6 mg/kg. Given a surface soil EPC of 7.33E-5 mg/kg and a LOAEL-EEQ of 1.44, the LOAEL-based EcoPRG is 5.1E-5 mg/kg.

15.7.2 Sediment

COPEC NOAEL and LOAEL concentrations can be estimated using EPCs and EEQs from the refined food chain models (**Appendix O** and **Table 15-10**). As discussed in **Section 15.1**, there are two final COPECs in the Goose Prairie Creek, Harrison Bayou, and/or Central Creek watersheds that require the calculation of food web-based EcoPRGs: mercury and thallium. These calculations are presented in the following subsections. Note that silver is not included in this subsection as this COPEC is a direct contact hazard, not a food chain hazard (**Table 15-10**).

Mercury. As only the Bank Swallow had an EEQ above 1 (**Table 15-10**), food web-based EcoPRGs are necessary for this receptor.

- Bank Swallow: Given a sediment EPC of 0.265 mg/kg and a NOAEL-EEQ of 1.42, the NOAEL-based EcoPRG is 0.19 mg/kg. Given a sediment EPC of 0.265 mg/kg and a LOAEL-EEQ of 0.142, the LOAEL-based EcoPRG is 1.9 mg/kg.

Thallium. As two receptors in three different watersheds had EEQs above 1 (**Table 15-10**), food web-based EcoPRGs are necessary for each receptor separately, except as noted below for the Raccoon (Louisiana Black Bear).

- Raccoon (Goose Prairie Creek Watershed): Given a sediment EPC of 0.702 mg/kg and a NOAEL-EEQ of 3.44, the NOAEL-based EcoPRG is 0.20 mg/kg. Given a

sediment EPC of 0.702 mg/kg and a LOAEL-EEQ of 0.344, the LOAEL-based EcoPRG is 2.0 mg/kg.

- Raccoon (Harrison Bayou Watershed): Given a sediment EPC of 0.60 mg/kg and a NOAEL-EEQ of 2.93, the NOAEL-based EcoPRG is 0.20 mg/kg. Given a sediment EPC of 0.60 mg/kg and a LOAEL-EEQ of 0.293, the LOAEL-based EcoPRG is 2.0 mg/kg.

- Raccoon (Central Creek Watershed): Given a sediment EPC of 0.71 mg/kg and a NOAEL-EEQ of 3.48, the NOAEL-based EcoPRG is 0.20 mg/kg. Given a sediment EPC of 0.71 mg/kg and a LOAEL-EEQ of 0.348, the LOAEL-based EcoPRG is 2.0 mg/kg.

- Raccoon (Louisiana Black Bear) (Goose Prairie Creek Watershed): As this receptor is a surrogate for a listed threatened or endangered species (the Louisiana black bear), EcoPRGs may only be calculated based on the NOAEL, per TCEQ guidance (TNRCC, 2001). Given a sediment EPC of 0.702 mg/kg for thallium and a NOAEL-based EEQ of 1.93, the NOAEL-based EcoPRG is 0.36 mg/kg.

- Raccoon (Louisiana Black Bear) (Harrison Bayou Watershed): As this receptor is a surrogate for a listed threatened or endangered species (the Louisiana black bear), EcoPRGs may only be calculated based on the NOAEL, per TCEQ guidance (TNRCC, 2001). Given a sediment EPC of 0.60 mg/kg for thallium and a NOAEL-based EEQ of 1.65, the NOAEL-based EcoPRG is 0.36 mg/kg.

It should be noted that there is considerable uncertainty associated with the Raccoon and Raccoon (Louisiana Black Bear) EEQs and calculated EcoPRGs for thallium. These uncertainties relate to the sediment-to-aquatic invertebrate bioaccumulation pathway and to background issues (**Section 15.8.2**).

Based on the results of the sediment toxicity tests and the weight of evidence discussion (**Sections 15.2** and **15.6**), the lead NOAEL and LOAEL concentrations for direct contact survival toxicity are estimated to be 246 and 352 mg/kg, respectively. The lead NOAEL and LOAEL concentrations for direct contact growth toxicity are estimated to be 191 and 246 mg/kg, respectively.

15.8 Uncertainty Analysis

A number of important uncertainties are associated with the BERA. These are discussed in the following subsections.

15.8.1 Sediment Toxicity

Sediment toxicity tests were conducted with sediment samples collected from areas of the site that are usually inundated, but because of prolonged drought conditions, were devoid of water at the time of sampling. In order to conduct the toxicity tests, it was necessary to re-hydrate the

sediment samples in the laboratory. The fact that the samples were dry for an extended period of time in situ and then re-hydrated in the laboratory introduces a significant level of uncertainty to the results of the sediment toxicity tests. In **Section 14.2.6** it was suggested that under normal saturated sediment conditions, levels of AVS would be much greater at LHAAP than during the drought conditions present in the fall of 2006 because the anoxic conditions necessary for the formation and retention of sulfides in the sediment only occur when surface water overlies the sediment. Greater levels of AVS in sediment would be expected to result in much lower metals bioavailability, and therefore reduced sediment toxicity to sensitive benthic invertebrates (however, as discussed in **Section 14.2.6**, there may be a brief time window after flooding and before AVS generation when benthic infauna may be subjected to higher metals toxicity). The magnitude of toxicity reduction due to the presence of elevated AVS during normal (non-drought) conditions is not known, however, it could be significant. Stagnant bottom water of Goose Prairie Creek Cove (Caddo Lake) would be expected to be anoxic during extended periods of the year, thereby resulting in the generation of AVS. Thus, the finding of sediment toxicity in the cove, likely related to elevated concentrations of lead (**Section 14.2.5**), may be atypical and primarily related to the desiccated condition of the sediment that resulted from the drought conditions occurring prior to, and during, the BERA sediment sampling. It should also be noted that during drought conditions there would be no benthic organisms present in the sediment, and therefore, no toxicity. In other words, the same ambient conditions (i.e., lack of overlying water) that would result in higher potential of toxicity to the benthic invertebrate community due to the absence of AVS also precludes the presence of the benthic invertebrate community, which typically require saturated sediments covered by water.

Another source of uncertainty associated with the sediment toxicity evaluation involves the changeouts of overlying water that were performed by the analytical laboratory twice per day for two days to stabilize the test condition pH (see **Section 14.2**). Although water changeouts are allowed as part of the standard toxicity testing methodology, the re-hydration of the sediment samples and subsequent water removal may have reduced COPEC mass in the sediment by eliminating suspended particles, and/or any COPEC that had solubilized or partitioned into the water column from the sediment.

As described in **Section 14.2**, overlying water with the standard toxicity test hardness of 88 mg/L was used for the Lake sediments rather than water with hardness that was more typical of waters in the LHAAP vicinity, which are much softer. The use of the harder water was done to buffer the pH fluctuations that were observed during the test preparation for the Lake sediments. However, there is a positive correlation between hardness and the tendency of toxic metals to form insoluble precipitates that are not available for biological uptake by organisms. Therefore, increasing the hardness of the water in the Lake (cove) sediment chambers may have decreased observed toxicity compared to what would be expected under ambient conditions with softer

water. However, under ambient conditions it is expected that the lake sediment would also be typically covered with water, and under these conditions AVS would likely form and buffer at least some, if not all, of the higher toxicity expected from softer waters (see above). Therefore, the actual toxicity thresholds of the LHAAP sediments, especially the lake sediments, have some uncertainty.

15.8.2 Thallium Sediment EEQs

There is considerable uncertainty associated with the Raccoon and Raccoon (Louisiana Black Bear) thallium sediment EEQs and calculated EcoPRGs. The most significant uncertainty is due to the fact that the vast majority (i.e., 93 percent) of the estimated hazard for these two receptors is from the sediment-to-aquatic invertebrate bioaccumulation pathway, and a site-specific thallium BAF could not be developed for this pathway due to unusually elevated aquatic worm detection limits (**Section 14.2.3**). Because of this, the Tier 1 thallium BAF of 4.5 was used to estimate COPEC concentrations in aquatic invertebrates. However, this BAF of 4.5 is based on an assumption by USEPA (1999a) that thallium bioaccumulates in a similar fashion to other metals for which BAF data are available. The BAF is actually based on the average of six BAFs for other inorganic chemicals (USEPA, 1999a): cadmium, chromium, copper, lead, mercury, and zinc. All of these metals are known to be bioaccumulators in either sediment or soil (**Appendix A**). As thallium in not a known sediment bioaccumulator (**Appendix A**), this is an extremely conservative assumption. Surrogate inorganic BAFs were estimated from known values of other Tier 1 metals and presented in **Volume I**, **Table 7-23,** and were calculated as 2.1 and 0.42, respectively, for the Step 3 Tier 1 and Tier 2 SLERA. These surrogate BAFs were used for inorganics for which no BAFs were available in the literature (i.e., chloride, manganese, nitrate, sulfate, and vanadium). If the Tier 1 surrogate inorganic BAF was used, instead of the BAF of 4.5, the thallium EcoPRG would increase by a factor of approximately 2.1. Additionally, if the Tier 2 surrogate inorganic BAF was used, instead of the BAF of 4.5, the thallium EcoPRG would increase by a factor of approximately 11. A literature search was conducted to identify general invertebrate uptake information for thallium. There is little readily available general invertebrate uptake information for thallium. The *Guidance for Developing Ecological Soil Screening Levels* (USEPA, 2005) does not provide terrestrial invertebrate uptake data for thallium, although information is presented for 15 other metals. Borgmann et al. (1998) reports that uptake from sediment to *Hyalella* (an amphipod invertebrate) ranged from 0.47 to 1.44, and averaged 1.01, for Lake Ontario sediments. These thallium uptake values are also less than the surrogate sediment uptake value of 2.1 that was used in the BERA. If this average uptake value of 1.01 is used, the original estimated thallium EcoPRG of 0.36 mg/kg for sediment (**Section 16.1.2**) would increase by a factor of 4.4 (original BAF of 4.5 divided by new BAF of 1.01), to 1.6 mg/kg. As all LHAAP watershed thallium EPCs are below 1.6 mg/kg (see **Section 16.1.4**), no further action for thallium in sediment is recommended.

A second important uncertainty is whether or not thallium in sediment at LHAAP is background-related. Based on information presented in Attachment 3 of **Appendix F** (**Volume I**), two of the 55 Central Creek sediment samples analyzed for thallium had detectable concentrations of 1.74 and 4.11 mg/kg. None of the 28 background samples had detectable thallium concentrations; however, the reporting limits in the background samples ranged from 1.3 to 22 mg/kg, with a mean of 8.2 mg/kg. These reporting limits are much higher than those for Central Creek, which were generally close to 1 mg/kg. Thallium concentrations observed in the Central Creek samples would thus be non-detect in the background samples based on these differences in reporting limits. Two of the 41 Harrison Bayou samples analyzed for thallium had detectable concentrations of 1.6 and 1.83 mg/kg. These concentrations were only slightly above their respective reporting limits. The Harrison Bayou reporting limits averaged 0.9 mg/kg, and were again much lower than the reporting limits from the background study. Thallium concentrations observed in the Harrison Bayou samples would thus also be non-detect in the background samples based on these differences in reporting limits. Finally, the average background reporting limit of 8.2 mg/kg was higher than the average Goose Prairie Creek sample reporting limit of 3.4 mg/kg. This information, plus geochemical evaluation results for Goose Prairie Creek (Attachment 3 of **Appendix F** in **Volume I**) strongly suggest that thallium in sediment is related to background. However, without background data with similar reporting limits to on-site data, whether thallium is background-related remains an uncertainty.

15.8.3 Interpretation of EEQs

The EEQs calculated for the refined BERA food chain model carry the same uncertainties as those previously generated during Step 3, and as discussed in **Section 8.10** (**Volume I**). These uncertainties must be clearly understood during the interpretation of the BERA results at the risk management stage. The most important consideration is that even after site-specific data are used in the food chain model, EEQs can only suggest that there is a potential adverse hazard for ecological receptors; an EEQ greater than one does not necessarily mean that ecological receptors have been or will be adversely impacted. General site observations, in addition to field studies such as the RSA effort, have not documented a paucity of ecological receptors at the Installation. If EEQs were an accurate reflection of hazard to ecological systems, it would be expected that populations would be significantly reduced at the Installation, since EEQs greater than 1 were identified by the BERA food chain model (Tannenbaum et al., 2003a).

15.8.4 North Cove Sediment Lead

As noted in **Section 14.2.5**, site-specific aquatic toxicity test results indicate that lead in the north Goose Prairie Creek Cove area of Caddo Lake may be the causative agent for the reduced survival and growth observed in aquatic invertebrates. However, it is important to consider that north cove sediment samples were placed along a transect that was directly in line with a duck blind that was located on the western edge of the cove (see **Section 15.2.5** for additional

information on this issue). These sample locations were historical locations determined in the past by the USACE and previous contractors to have elevated lead concentrations. Therefore, at least some of the lead in these samples could very well be from weathered lead shot associated with past hunting events rather than the result of historical site activities.

15.8.5 Estimation of EcoPRGs for COPECs with Regression-Based Uptake Factors

There is some uncertainty associated with the EcoPRGs estimated for those COPECs that utilize soil-to-terrestrial invertebrate, soil-to-plant, and/or sediment-to-aquatic invertebrate BAFs derived from a regression equation that is dependent on the concentration in the medium of concern. This is because the original EPC used to estimate the receptor EEQ is not linearly related to the COPEC BAF. It is possible that the EcoPRGs estimated in **Section 15.7** underestimate ecological hazard due to the fact that most BAF regression equations predict increased bioaccumulation at lower concentrations compared with higher concentrations. However, the potential impact of this uncertainty is considered to be relatively low, especially given the conservative assumptions retained in the food chain modeling and EEQ approach.

15.8.6 Surface Water Monitoring Discussion

Several preliminary COPECs in surface water (i.e., aluminum, cadmium, copper, iron, and lead) were determined to be background-related (**Section 15.6**) and no EcoPRGs for surface water were considered. Subsequent sampling for lead in surface water in Goose Prairie Creek determined that lead was indeed background related (**Section 10.3.6.1; Appendix F-1, Volume I**). However, as the determination of background COPECs in surface water is associated with some uncertainty (**Volume I**, **Section 10.4**, **Appendix F**, and **Appendix I**), risk managers may consider surface water monitoring for these four remaining COPECs, especially in the Goose Prairie Creek, Central Creek, and Harrison Bayou watersheds.

15.8.7 Evaluation of Additional Samples Collected at Longhorn

The data set that was used as the basis of most analyses in this Step 3/BERA ("BERA dataset") is presented in **Tables 6-2** through **6-12** in **Volume I** of this report, and represents all the samples collected at the Installation at the time the Step 3/BERA effort was initiated. The latest date of sample collection for the BERA dataset was September 9, 2003. However, environmental investigations have been ongoing at LHAAP during the development of the Step 3/BERA report, and additional environmental data have been obtained from investigative sampling efforts since September 9, 2003. Some of these additional samples have already been accounted for and incorporated into the Step 3/BERA decision-making process, notably:

- Surface water and sediment samples collected in September, 2004 as part of a "Data Gaps" study were evaluated during Step 3 by comparing concentrations detected in those samples to concentrations in the Step 3/BERA dataset (see **Section 8.14** and **Appendix G** in **Volume I** of this report).

- Additional soil samples collected in February, 2006 from the Pistol Range, located in the Waste Sub-Area were used to modify the EPC for lead in the BERA food chain model (**Section 15.1**).
- An elevated concentration of mercury in sediment at sample location 49SD65 was noted during the COPEC refinement step (see **Section 10.2.7.1** in **Volume I**) and used as a reason to retain mercury as a final COPEC in sediment.

However, other environmental investigations at the Installation resulted in the collection of additional samples that have not been evaluated in the Step 3/BERA. To identify these samples, all analytical data in samples collected from soil, surface water, and sediment since September 9, 2003 were queried in the project database. Samples already evaluated in the ERA (including the samples described in the first two bullets of the preceding paragraph) and samples that are not appropriate for use (e.g., soil samples deeper than 3 feet bgs) were eliminated so that only ecologically relevant samples that have not been included in the ecological investigation to date were selected. The query identified 145 soil samples in the Industrial Sub-Area, and two soil samples in both the Low Impact Sub-Area and Waste Sub-Area. Several sediment samples were also identified, including four from the Goose Prairie Creek watershed and three from the Central Creek watershed. Some surface water samples were identified, but were affiliated with quarterly USACE water quality sampling programs, and not considered appropriate for further risk assessment evaluation. Most of the Industrial Sub-Area soil samples and the two samples from the other sub-areas were collected as part of an investigation of sumps near known process facilities at Longhorn (also known as the "Site 35/36" investigation). The remaining samples were collected over the past few years primarily to confirm/delineate known or suspected areas of contamination. As such, nearly all of the samples in the post-BERA dataset are biased samples that were collected near areas with intense historical use in the Production Area of Longhorn.

An evaluation of the post-BERA data and a discussion regarding impacts, if any, the data would have on the results and conclusions of the Step 3/BERA report, is provided in the following sections. A summary of chemicals and concentration ranges detected in the post-BERA dataset for each sub-area or watershed was developed. The mean and maximum concentrations of all detected chemicals were then compared with the BERA dataset. All chemicals in the post-BERA dataset whose mean or maximum concentrations exceeded the BERA dataset and chemicals that were detected in the post-BERA dataset but were not detected in the BERA dataset, were carried forward for further evaluation and analysis to determine if they would change conclusions of the risk assessment. Because the primary goal of this exercise was to determine if ecological hazards were potentially underestimated in the Step 3/BERA report due to the omission of the post-BERA data, it was assumed that chemical analytical results that were generally lower than the BERA dataset (as reflected by the comparison of means and MDCs) were relatively innocuous, and would not impact the conclusions of the risk assessment.

After the post-BERA dataset evaluation was completed, USFWS personnel brought to Shaw's attention that an additional USFWS sampling program had recently been conducted at LHAAP (USFWS, 2005). Thirty-two surface soil locations were sampled in the Production Area, which includes the portion of the Industrial Sub-Area that was most heavily involved in munitions manufacturing and rocket testing. Analytes included metals, PCBs, perchlorate, and pesticides. The data from this study were not transferred to Shaw, and were therefore not included in the BERA or post-BERA dataset evaluation. However, overall concentrations of chemicals detected in surface soil were low, and the report states "In comparison to available ecological screening criteria, none of the detected surficial soil contaminant concentrations were at levels likely to adversely affect ecological resources." Therefore, although the omission of these data is regrettable, the results indicate that no change in BERA conclusions is necessary.

15.8.7.1 Evaluation of Post-BERA Soil Data

Additional soil samples for all three sub-areas (Industrial, Low Impact, and Waste) were collected after the BERA dataset was frozen, and are discussed in the following paragraphs.

Industrial Sub-Area

Table 15-13 presents a summary of the post-BERA data results for samples collected in the Industrial Sub-Area. Chemicals whose mean or maximum concentrations exceeded those in the BERA dataset, or that were not detected in the BERA dataset, are presented in **Table 15-14**. Seventeen chemicals had higher MDCs and 36 chemicals had higher means in the post-BERA dataset than in the BERA dataset. Additionally, 18 chemicals were detected in the post-BERA dataset that were not detected in the BERA dataset. 95% UCLs were calculated for all of these chemicals, and compared to ESVs. Only two chemicals, MCPP and heptachlor epoxide, would have been added as initial COPECs using a total, combined dataset (i.e., BERA plus post-BERA data) in the Step 3 COPEC screening step (**Table 15-14**). All other chemicals would have the same decision in the COPEC screen if the post-BERA data were incorporated, i.e., the selection of initial COPECs would not change). Both MCPP and heptachlor epoxide would be selected as initial COPECs because they are bioaccumulative compounds. Although the HQ_{screen} value for MCPP was elevated (37), this chemical was only detected in one out of 152 samples in the Industrial Sub-Area. Therefore, MCPP is not a relevant chemical for ecological exposure because it was detected so infrequently. The HQ_{screen} value for heptachlor epoxide was below 1 for the combined data set (0.1). Furthermore, its detection frequency did not exceed 5 percent in the combined dataset. Therefore, heptachlor epoxide is not of concern for ecological exposure because its concentrations are below conservative benchmarks, and it was detected infrequently.

95% UCLs for chemicals that were selected as COPECs using both the original BERA dataset and the combined dataset were further evaluated. Chemicals that had UCLs that were more than 10 percent higher than the UCLs that were used during previous food chain modeling efforts

were re-evaluated to ensure that the higher exposure concentrations reflected by the combined data set do not affect ERA conclusions. Six chemicals had UCLs that were at least 10 percent higher in the combined dataset compared with the original BERA dataset: Lead (+ 38%), mercury (+ 478%), zinc (+ 11%), alpha-chlordane (+ 3060%), gamma-chlordane (+ 4022%), and heptachlor (+ 400%). Because most of the post-BERA samples were collected from areas adjacent to Production sites, the substantially higher concentrations of pesticides in these samples is not unexpected due to the maintenance that was required to limit nuisance plant and animal species in these areas. Zinc was identified as a final COPEC in soil in this sub-area, so the new UCL was entered into the refined food chain model used in the BERA. None of the terrestrial ecological receptors resulted in a soil exposure EEQ greater than 1 for zinc exposure. UCLs for the lead, mercury, alpha-chlordane, gamma-chlordane, and heptachlor based on the combined dataset were entered into the Step 3 food chain models. All terrestrial receptors had EEQs less than 1 for exposure to these chemicals.

Even though mercury was not determined to be of concern for ecological receptors, the considerable change in the mercury EPC warrants additional discussion. The nearly five-fold increase in the EPC is due to the inclusion of a detection of 778 mg/kg at sample location 49SD65. This sample result was noted in the COPEC refinement discussion during Step 3 (see **Section 10.2.7.1** in **Volume I**), where it was originally classified as a sediment sample. However, this sample was collected from a very shallow, grassy area where a drainage ditch was believed to exist adjacent to a laboratory building at Site 49. No ditch is present in this area, though, and no aquatic habitat features (e.g., standing or running water, hydrophilic vegetation, benthic communities, etc.) exist at this sample location. Therefore, this sample was re-classified as a soil sample and included in the Industrial Sub-Area soil evaluation. Concern of a large mercury source area in the vicinity of sample 49SD65 is reduced when adjacent sample results are taken into account. **Figure 15-1** shows the concentrations of mercury in surrounding soil and sediment samples. Two soil samples just to the west of 49SD65 (49SB32 and 49SS47) had somewhat elevated concentrations of mercury (84.2 mg/kg and 3.76 mg/kg, respectively), and one sample to the east (49SB17) also had a mercury concentration that exceeded 1 mg/kg (2.12 mg/kg). All other samples in the vicinity were non-detect, or had trace levels of mercury. If a polygon is drawn around these sample locations, excluding other adjacent sample locations, the area affected by elevated mercury is approximately 0.3 hectares (ha), which is smaller than the home range for all terrestrial ecological receptors evaluated in the BERA except the Deer Mouse. If the average concentration of the three soil sample locations (778, 84.2, and 3.76 mg/kg) within this area is used as the representative mercury concentration in soil and entered into the BERA food chain model, the resulting Deer Mouse EEQ is 0.09. Therefore, mercury does not appear to be problematic for terrestrial exposure. The two sediment sample locations to the north/northeast of LHAAP-49 that flow into Goose Prairie Creek were non-detect for mercury.

The three sediment samples collected from the southern edge of the site had trace levels of mercury. Therefore, mercury does not appear to be problematic for aquatic exposure.

It is concluded that the inclusion of the post-BERA samples does not affect ERA recommendations for soil in the Industrial Sub-Area.

Low Impact Sub-Area

Table 15-15 presents a summary of the post-BERA data results for samples collected in the Low Impact Sub-Area. Chemicals whose mean or maximum concentrations exceeded those in the BERA dataset, or that were not detected in the BERA dataset, are presented in **Table 15-16**. One chemical had a higher MDC and six chemicals had higher means in the post-BERA dataset than in the original BERA dataset. One chemical (thallium) was detected in the post-BERA dataset, but not in the BERA dataset. 95% UCLs were calculated for these chemicals, and compared to ESVs. The COPEC selection decision did not change for any chemical using the combined dataset (i.e., BERA plus post-BERA data) in the Step 3 COPEC screening step (**Table 15-16**).

95% UCLs for chemicals that were selected as COPECs using both the original BERA and the combined datasets were calculated. No chemicals had UCLs that were more than 10 percent higher than the UCLs that were used during previous food chain modeling efforts. Thus, the impact of the addition of the post-BERA samples on the risk assessment results are considered inconsequential.

It is concluded that the inclusion of the post-BERA samples does not affect ecological risk recommendations for soil in the Low Impact Sub-Area.

Waste Sub-Area

Table 15-17 presents a summary of the post-BERA data results for samples collected in the Waste Sub-Area. Chemicals whose mean or maximum concentrations exceeded those in the BERA dataset, or that were not detected in the BERA dataset, are presented in **Table 15-18**. Two chemicals had higher MDCs and eight chemicals had higher means in the post-BERA dataset than in the BERA dataset. No chemicals were detected in the post-BERA dataset that were not detected in the BERA dataset. 95% UCLs were calculated for all of these chemicals, and compared to ESVs. The COPEC selection decision did not change for any chemical using a total, combined dataset (i.e., BERA plus post-BERA data) in the Step 3 COPEC screening step (**Table 15-18**).

95% UCLs for chemicals that were selected as COPECs using both the original BERA and the combined datasets were calculated. Chemicals that had UCLs that were more than 10 percent higher than the UCLs that were used during previous food chain modeling efforts were re-

evaluated to ensure that the higher exposure concentrations reflected by the combined data set do not affect ERA conclusions. Three chemicals had higher UCLs in the combined dataset compared with the BERA dataset: copper (+ 10.5%), iron (+ 32%), and vanadium (+ 10.6%). None of these chemicals were previously identified as final COPECs in soil in this sub-area, so the new UCL for each chemical was entered into the Step 3 food chain models. Based on the new UCLs for both iron and copper, all terrestrial receptors had EEQs less than 1. For vanadium, the Short-Tailed Shrew had an EEQ of 2.94 based on the combined UCL. The previous EEQ for this receptor using the BERA dataset was also above 1, however (EEQ = 2.67). However, vanadium was eliminated as a final COPEC during Step 3 because it was determined to be background-related (see **Section 10.1.10.2** in **Volume I**).

Post-BERA Soil Data Summary

It is concluded that the inclusion of the post-BERA samples does not affect ecological risk recommendations for soil in the Waste Sub-Area.

15.8.7.2 Evaluation of Post-BERA Sediment

Additional sediment samples for Goose Prairie Creek and Central Creek were collected after the BERA dataset was frozen, and are discussed in the following paragraphs.

Goose Prairie Creek Watershed

Table 15-19 presents a summary of the post-BERA data results for samples collected in the Goose Prairie Creek watershed. Samples were only analyzed for lead and mercury. Neither the MDC nor the mean for lead or mercury were higher in the post-BERA dataset than in the BERA dataset (**Table 15-20**). Therefore, no further evaluation for Goose Prairie Creek sediment is necessary.

Central Creek Watershed

Table 15-21 presents a summary of the post-BERA data results for samples collected in the Central Creek watershed. Samples were only analyzed for nitroaromatic compounds. Four nitroaromatics were detected in sediment samples in the post-BERA dataset. None had been detected in sediment previously (**Table 15-22**). Although the HQ_{screen} values for all chemicals except for 2-amino-4,6,-DNT were elevated, the chemicals would not be selected as COPECs due to their very low frequency of detection (i.e., less than 3 % for all chemicals). However, it should be noted that sample location 29SD46 had extremely elevated concentrations of all four nitroaromatics detected (e.g., TNT = 26,000 mg/kg). This sample was collected from a former outfall ditch at the northeast end of the TNT Cooling Water Drain Line (South) in Site 29. **Figure 15-2** provides the concentrations of all soil and sediment sample concentrations of TNT and its breakdown products (2,4-DNT and 2,6-DNT) in samples near location 29SD46. A sediment sample from location 29SD30, which is in the same ditch approximately 100 feet

northeast (downgradient) of sample 29SD46, was non-detect for TNT and its breakdown products. However, three samples further downgradient had detectable-- but comparably much lower-- concentrations of nitrotoluenes (29SD13: 51 mg/kg TNT; GPS-12: 6.21 mg/kg TNT; 29SB15: 110 mg/kg TNT, 6.2 mg/kg 2,4-DNT). TNT and its breakdown products were non-detect in 29SD29, the furthest downgradient ditch sample leading off of the site. Therefore, it is unlikely that nitrotoluenes are being transported off site, and potentially into Central Creek. Finally, one soil sample directly to the north of 29SD46 (29SD45) had a trace amount of TNT (0.41 mg/kg).

The TNT concentrations in the ditch samples 29SD13 and 29SB15 exceed the soil screening value of 30 mg/kg, and the 2,4-DNT detection at 29SB15 exceeds the soil screening value of 1.28 mg/kg, as well. If a polygon is drawn around the sample locations with detected concentrations of nitrotoluenes, extending approximately half-way to adjacent sample locations that were non-detect, the area affected by elevated nitrotoluenes is approximately 2.3 ha, which is smaller than the home range for all terrestrial ecological receptors evaluated in the BERA except the Deer Mouse and the Short-Tailed Shrew. If the average concentrations of the dry sediment/soil samples within this area are used as the representative TNT, 2,4-DNT, and 2,6-DNT concentrations in soil and entered into the BERA food chain model, the resulting Deer Mouse and Short-Tailed Shrew EEQs exceed a value of 1 (e.g., TNT EEQs of 550 and 860 for these two receptors, respectively). Therefore, it may be appropriate to apply ecological cleanup goals derived in the Waste Sub-Area for these three chemicals to this nitrotoluene hotspot in LHAAP-29 for the protection of small-range mammalian receptors, as recommended in the BERA.

Because these chemicals were not identified as initial COPECs previously, and would not be included even after the addition of the post-BERA samples to the database due to low frequency of detection and lack of bioaccumulation potential, an evaluation of how the elevated concentrations in sample location 29SD46 would impact food chain model results was not performed. However, the three chemicals with elevated COPEC concentrations in this sample that had HQ_{screen} values greater than 1 (i.e., TNT, 2,4-DNT, and 2,6-DNT) were all considered final COPECs in soil in the Waste Sub-Area. Because the ditch where sample 29SD46 was collected is typically dry, it is recommended that ecological clean-up options developed for soil in the Waste Sub-Area also focus on sediment and soil in and near this ditch.

Post-BERA Sediment Data Summary

It is concluded that the inclusion of the post-BERA samples does not affect ecological risk recommendations for sediment in the Central Creek watershed. However, very high nitroaromatic concentrations were detected in one sample location (29SD46). It is thus

recommended that soil clean-up options for TNT, 2,4-DNT, and 2,6-DNT in the Waste Sub-Area be considered applicable to this sediment sample location.

15.8.8 Potential Impacts to Plants and Soil Invertebrates

As discussed in **Section 11.2** (**Volume I**), and **Section 15.3**, an assessment endpoint was developed based on the protection of plants and soil invertebrates. However, it was agreed by the Longhorn stakeholders that EcoPRGs would not be developed based on the protection of these organisms, and no Risk Questions were developed or hypotheses tested to specifically address concerns for these base of the food chain organisms. **Sections 7.1.1.1** through **7.1.1.3** provide comparisons of concentrations detected in soil in the Industrial, Low Impact, and Waste Sub-Areas, respectively, to benchmarks protective of earthworms and plants. The following exceedances were noted:

Industrial Sub-Area

- Earthworm Benchmark Exceedances: mercury
- Plant Benchmark Exceedances: aluminum, chromium, mercury, selenium, vanadium, and zinc

Low Impact Sub-Area

- Earthworm Benchmark Exceedances: None
- Plant Benchmark Exceedances: chromium, manganese, vanadium, and zinc

Waste Sub-Area

- Earthworm Benchmark Exceedances: barium and TNT
- Plant Benchmark Exceedances: aluminum, barium, chromium, lead, vanadium, zinc, and TNT

Therefore, there is some uncertainty regarding the potential impacts of these chemicals to plants and terrestrial invertebrates. As noted in previous portions of the report, although formal vegetation surveys have not been conducted, no areas of stressed vegetation have been noted by field biologists at the Installation. Additionally, populations of higher trophic-level receptors that rely upon plants and terrestrial invertebrates as a food source (e.g., small mammals) appear to be well established at the Installation. During the soil-earthworm uptake study that was conducted as part of the BERA, it was noted that mean survival of earthworms from on-site samples was actually greater than the laboratory control of 94 percent (**Appendix N**). Because the BERA sample locations were preferentially placed in areas of highest contamination (as

identified from historical sample results), this observation provides strong evidence that toxicity to earthworms (or other terrestrial invertebrates) is not a concern at LHAAP.

			RAC	**1.25E+01**	**1.25E+00**
			RAC (LBB)	**1.76E+00**	1.76E-01
			AW	**1.44E+01**	**1.44E+00**

Notes:

Shaded cells indicate that the EEQ exceeds 1.

Receptors: AW = American Woodcock; DM = Deer Mouse; RAC = Raccoon; RAC (LBB) = Raccoon (Louisiana Black Bear); RF = Red Fox; RTH = Red-Tailed Hawk; STS = Short-tailed Shrew; TBEB = Townsend's Big-Eared Bat.

BERA = Baseline ecological risk assessment

COPEC = Chemical of potential ecological concern

EEQ = Ecological effects quotient

LOAEL = Lowest observed adverse effects level

NA = Not applicable; avian toxicity reference values (TRV) are not available for hexavalent chromium.

NOAEL = No observed adverse effects level

Table 15-10
EEQs for Final COPECs Associated with Sediment Exposure
Final BERA Food Chain Model Results

Final COPEC	Medium	Watershed	Receptor	EEQ-NOAEL	EEQ-LOAEL
Metals					
Lead	Sediment	Goose Prairie Creek	BS	8.73E-01	8.73E-02
Mercury	Sediment	Goose Prairie Creek	BS	1.42E+00	1.42E-01
			BK	8.31E-01	8.31E-02
Silver	Sediment	Goose Prairie Creek		NA	
Thallium	Sediment	Goose Prairie Creek	RAC	3.44E+00	3.44E-01
			RAC (LBB)	1.93E+00	1.93E-01
		Harrison Bayou	RAC	2.93E+00	2.93E-01
			RAC (LBB)	1.65E+00	1.65E-01
		Central Creek	RAC	3.48E+00	3.48E-01
			RAC (LBB)	4.74E-01	4.74E-02

Notes:

Shaded cells indicate that the EEQ exceeds 1.

Receptors: BK = Belted Kingfisher; BS = Bank Swallow; RAC = Raccoon; RAC (LBB) = Raccoon (Louisiana Black Bear).

BERA = Baseline ecological risk assessment

COPEC = Chemical of potential ecological concern

EEQ = Ecological effects quotient

LOAEL = Lowest observed adverse effects level

NA = Not applicable; silver was selected as a final COPEC only because of concerns regarding direct toxicity.

NOAEL = No observed adverse effects level

Notes:

Sample locations are shown on Figure 14-6.

SS = surface soil, SB = soil boring, SED = dry sediment.

These sample locations are associated with the small rodent trapping locations used in the RSA Study performed by USACHPPM (2006).

Notes:

[a] Sample results from near surface soil and dry sediment used, see Table 15-11 for sample list.

[b] Chemicals presented are final COPECs selected for soil at LHAAP.

[c] Areas represent the three rodent sperm analysis (RSA) Study areas, see Figure 14-6 for details.

TCDD TEQ = 2,3,7,8-TCDD toxicity equivalent concentration.

Bolded concentrations reflect higher concentrations in the Post-BERA dataset than the BERA dataset.

Table 15-14
Comparison of Concentrations[a] Between the BERA Dataset and Post-BERA Dataset
Total Soil: Industrial Sub-Area

Notes:

[a] Detection frequency, concentrations, and COPEC selection information for chemicals using the original BERA dataset can be found in Table 6-17 of the Volume I BERA report.

[b] Only chemicals whose maximum or mean concentrations were higher in the Post-BERA data compared with the original BERA dataset, or that were detected in the Post-BERA dataset but not in the original data, are included. Essential nutrients are not includ

[e] See Table 6-14, Volume I of the BERA unless noted otherwise.

[d] HQ_{screen} is calculated as the 95% UCL divided by the ecological screening value (ESV).

[e] No = Chemical is not chosen as a COPEC; Yes = Chemical is chosen as a COPEC.

[f] Rationale for exclusion of chemical as a COPEC:
(a) The screening concentration is less than the ESV.
(b) The detection frequency is less than 5 percent.

[g] Talmage, S.S., D.M. Opresko, C.J. Maxwell, C.J.E. Welsh, F.M. Cretella, P.H. Reno, and F.B. Daniel, 1999, Nitroaromatic Munition Compounds: Environmental Effects and Screening Values, **Rev. Environ. Contam. Toxicol.** 161:1-156, Springer-Verlag. Screening concentration used is the lowest of the Plant and Soil Invertebrate concentrations. Wildlife (shrew) values were not included as candidates for screening values. This is consistent with TCEQ's method of only using the Plant and Earthworm values to select their screening values.

Bolded concentrations reflect higher maximum and/or mean concentrations in the post-BERA set than the BERA dataset.

Notes:

[a] Detection frequency, concentrations, and COPEC selection information for chemicals using the original BERA dataset can be found in Table 6-19 of the Volume I BERA report.

[b] Only chemicals whose maximum or mean concentrations were higher in the Post-BERA data compared with the original BERA dataset, or that were detected in the Post-BERA dataset but not in the original data, are included. Essential nutrients are not includ

[e] See Table 6-14, Volume I of the BERA.

[d] HQ_{screen} is calculated as the 95% UCL divided by the ecological screening value (ESV). If the sample size was less than 10, the maximum detected concentration was used in place of the 95% UCL.

[e] No = Chemical is not chosen as a COPEC; Yes = Chemical is chosen as a COPEC.

[f] Rationale for exclusion of chemical as a COPEC:

(a) The screening concentration is less than the ESV.
(b) The detection frequency is less than 5 percent.

16.0 Step 8: Risk Management

Section 16.0 presents Step 8, and contains information to support risk management decisions including recommended ecological PRGs, a brief discussion on potential ecological impacts of remedial options, monitoring considerations, and other risk management considerations. Risk management is a distinctly different process from risk assessment. The risk assessment establishes whether an ecological hazard may be present and defines a range or magnitude of the estimated hazard. In risk management, the results of the risk assessment are integrated with other considerations to make and justify risk management decisions. Additional risk management considerations can include the implications of existing background levels of COPECs, available technologies, tradeoffs between human and ecological concerns, costs of alternative actions, and remedy selection. This section concludes with an SMDP.

16.1 Recommended Ecological PRGs

Based on the estimated NOAEL and LOAEL concentrations for the final COPECs presented in **Section 15.7**, EcoPRGs specific to LHAAP are calculated using the Rule of Five (Greenberg and Charters, 2005), as agreed to by stakeholders (February 9, 2006 Meeting; **Appendix K**). It should be noted that the Rule of Five is not published USEPA guidance and is used in this LHAAP BERA at the recommendation of USEPA (July 28, 2005 LHAAP meeting referenced in the January 18, 2006 response to USEPA Region 6 comments [USEPA Comment No.3]).

The Rule of Five is a process by which EcoPRGs may be selected or developed from available information presented in the BERA at CERCLA (and possibly other) contaminated sites. The Rule of Five provides a simple and logical method for the development of defensible cleanup goals following the ecological risk characterization. It also provides a flexible framework within the risk range from which a clean up number may be selected. It should be noted that a cleanup goal based on neither the NOAEL nor the LOAEL itself are typically selected as an EcoPRG for a given chemical (Greenberg and Charters, 2005). An exception to this approach is where the NOAEL EcoPRG is selected for a surrogate wildlife receptor that represents a listed threatened or endangered species such as the Townsend's Big-Eared bat as a surrogate for the Rafinesque's Big-Eared Bat, and the Raccoon (Louisiana Black Bear) as a surrogate for the Louisiana Black Bear. This exception is based on Texas risk assessment guidance (TNRCC, 2001), which states that EcoPRGs based on the NOAEL must be selected for listed threatened or endangered species (or their surrogates).

A cleanup goal can be selected within the NOAEL-LOAEL risk range for a particular assessment endpoint based on the consideration of points in a geometric progression (Greenberg and Charters, 2005):

$$A_n = A_0 \times r^{n-1}$$

To calculate the constant "r", the following equation is used:

$$r = e^{\left[\frac{\ln(A_n)-(A_0)}{n-1}\right]}$$

where: Node 2 = NOAEL x r^{2-1}
Node 3 = NOAEL x r^{3-1}
etc

and the LOAEL (Node 7) = NOAEL x r^{7-1}

The following schematic summarizes the Rule of Five approach:

Initial	← The Clean Up Goal is Within this Range →					Final
NOAEL	←				→	LOAEL
Node 1	Node 2	Node 3	Node 4	Node 5	Node 6	Node 7
The five nodes between the NOAEL and the LOAEL are typically considered as EcoPRGs. However, for threatened and endangered species, Node 1 is considered as the EcoPRG.						

The initial assumption is that the third point (or Node 4) above the low end of the risk range (the NOAEL) is protective of growth and reproduction endpoints. This point is also equivalent to the geometric mean of the NOAEL and LOAEL. If the basis of the risk range (as determined by the toxicological endpoint of the chemical's TRV) is survival or mortality, the initial point (or clean up goal) is recommended to be the second point above the NOAEL (or Node 3) (Greenberg and Charters, 2005). Thus, a value from within the NOAEL-to-LOAEL range that will be protective of ecological receptors is selected as the EcoPRG (except as discussed previously for surrogate receptors selected for listed threatened or endangered species). This EcoPRG is then considered with other site factors in reaching a risk management decision.

16.1.1 EcoPRG Selection for Final COPECs in Soil

Estimated NOAEL- and/or LOAEL-based EcoPRGs for soil were presented in **Sections 15.4.1** and **15.7.1** for the six final COPECs in the Waste Sub-Area that had an EEQ greater than 1 for at least one receptor (i.e., barium, lead, 2,4-DNT, 2,6-DNT, 2,4,6-TNT, and dioxin). These NOAEL- and LOAEL-based EcoPRGs are used to estimate final EcoPRGs based on the Rule of Five (discussed above). For listed threatened or endangered surrogate species (i.e., the Townsend's Big-Eared Bat and the Raccoon [Louisiana Black Bear]) the Rule of Five is not used, as Texas guidance (TNRCC, 2001) requires the use of the NOAEL-based EcoPRG. It should be noted that no EcoPRGs are required for the Industrial Sub-Area or the Low Impact Sub-Area because no final COPECs in soil were found to have unacceptable hazard for these two areas. In addition, results of the RSA application demonstrated that chemicals present in

Industrial Sub-Area soil are not harming maximally exposed site mammals. All terrestrial receptors except the Short-Tailed Shrew and the Red Fox reflect exposure to surface soil (0 to 0.5 foot). The Short-Tailed Shrew and Red Fox reflect exposure to total soil (0 to 3 feet). EcoPRGs must be considered for both depths, depending on which receptors are potentially at risk. Recommended EcoPRGs in soil are presented for each receptor, and as each receptor is associated with a unique soil depth interval, these EcoPRGs need only be attained for this specific depth (see **Section 16.1.3** for further discussion related to attainment).

Barium. As four receptors had EEQs above 1 (**Section 15.7.1**), it is necessary to calculate EcoPRGs for each receptor, and the lowest EcoPRG is recommended for use in making risk management decisions (**Table 16-1**).

- Townsend's Big-Eared Bat: As this receptor is a surrogate for a listed threatened or endangered species (the Rafinesque's big-eared bat), the NOAEL-based EcoPRG is 252 mg/kg for surface soil, based on results of the refined food chain model. Based on results of the RSA, the NOAEL-EcoPRG is 300 mg/kg. As discussed in **Section 15.5**, there are benefits and limitations associated with the values from both of these sources.

- Raccoon: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 208 and 808 mg/kg, respectively. As the barium LOAEL TRV is based on mortality (**Volume I**, **Table 7-25**) Node 3 (or 327 mg/kg for surface soil) is selected using the Rule of Five. If the NOAEL-EcoPRG from the RSA Study is used, Node 3 is 418 mg/kg.

- Deer Mouse: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 141 and 547 mg/kg, respectively. As the barium LOAEL TRV is based on mortality (**Volume I**, **Table 7-25**) Node 3 (or 222 mg/kg for surface soil) is selected using the Rule of Five. If the NOAEL-EcoPRG from the RSA Study is used, Node 3 is 367 mg/kg.

- Short-Tailed Shrew: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 331 and 1,283 mg/kg, respectively. As the barium LOAEL TRV is based on mortality (**Volume I**, **Table 7-25**) Node 3 (or 520 mg/kg for total soil) is selected using the Rule of Five. The NOAEL-EcoPRG from the RSA Study (300 mg/kg) is not appropriate to use as the initial NOAEL value, as it is lower than the food chain model NOAEL-based EcoPRG of 331 mg/kg, and when multiple NOAEL-based EcoPRGs are available that are protective of the same, or similar, endpoints, it is appropriate to use the highest NOAEL-based value in applying the Rule of Five (USEPA, 1997a; USACHPPM, 2000).

In conclusion, the lowest (most conservative) EcoPRGs for barium are as follows:

- Surface soil (0 to 0.5 feet) EcoPRG = 222 mg/kg, based on data from the refined food chain model for the Deer Mouse

- Surface soil (0 to 0.5 feet) EcoPRG = 300 mg/kg, based on data from the RSA Study, as this is the NOAEL-based EcoPRG for the Townsend's Big-Eared Bat. However, the RSA study is not used to develop the primary EcoPRG recommended in this BERA (**Section 15.7.1**).

- Total soil (0 to 3 feet) EcoPRG = 520 mg/kg, based on data from the refined food chain model for the Short-Tailed Shrew

It should be noted that the site-specific background concentrations for barium range from 116 to 136 mg/kg (**Volume I**, **Appendix F**, Table F-3). All of the recommended EcoPRGs (above) exceed this background range.

Lead. Only the American Woodcock had an EEQ above 1 (**Section 15.7.1**). Therefore, EcoPRGs are necessary for only this one receptor (**Table 16-1**).

- American Woodcock. NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model, and using the metallic lead TRV (see **Section 15.7.1**), were 255 and 763 mg/kg, respectively. As the lead NOAEL and LOAEL TRVs are based on reproduction (**Volume I**, **Table 7-25**), Node 4 (or 441 mg/kg for surface soil) is selected using the Rule of Five (Greenberg and Charters, 2005). The RSA NOAEL, which is based on observations of mammalian species, is not considered for the development of EcoPRGs for avian receptors.

In conclusion, the lowest (most conservative) EcoPRG for lead is as follows:

- Surface soil (0 to 0.5 feet) EcoPRG = 441 mg/kg, based on data from the refined food chain model for the American Woodcock

- No total soil (0 to 3 feet) EcoPRG is necessary, as no receptors potentially exposed to subsurface soil had EEQs greater than 1

It should be noted that the site-specific background concentrations for lead range from 18 to 20 mg/kg (**Volume I**, **Appendix F**, Table F-3). The recommended EcoPRG (above) exceeds this background range.

2,4-DNT. As two receptors had EEQs above 1 (**Section 15.7.1**), EcoPRGs are necessary for each receptor separately, and the lowest EcoPRG is recommended for use in making risk management decisions (**Table 16-1**).

- Short-Tailed Shrew: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 9.6 and 72 mg/kg, respectively. As the 2,4-DNT NOAEL and LOAEL TRVs are based on neurotoxicity and other non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 26 mg/kg for total soil) is selected using the Rule of Five. The NOAEL-EcoPRG from the RSA Study (0.0342 mg/kg) is not appropriate to use as the initial NOAEL value, as it is lower than the food chain model

NOAEL-based EcoPRG of 9.6 mg/kg, and the highest NOAEL-based EcoPRG should be selected for use in applying the Rule of Five (Greenberg and Charters, 2005).

- Red Fox: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 4.4 and 33 mg/kg, respectively. As the 2,4-DNT NOAEL and LOAEL TRVs are based on neurotoxicity and other non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 12 mg/kg for total soil) is selected using the Rule of Five (Greenberg and Charters, 2005. The NOAEL-EcoPRG from the RSA Study (0.0342 mg/kg) is not appropriate to use as the initial NOAEL value, as it is lower than the food chain model NOAEL-based EcoPRG of 4.4 mg/kg, and when multiple NOAEL-based EcoPRGs are available that are protective of the same, or similar, endpoints, it is appropriate to use the highest NOAEL-based value in applying the Rule of Five (USEPA, 1997a; USACHPPM, 2000).

In conclusion, the lowest (most conservative) EcoPRG for 2,4-DNT is as follows:

- Total soil (0 to 3 feet) EcoPRG = 12 mg/kg, based on data from the refined food chain model for the Red Fox

2,6-DNT. As three receptors had EEQs above 1 (**Section 15.7.1**), EcoPRGs are necessary for each receptor separately, and the lowest EcoPRG is recommended for use in making risk management decisions (**Table 16-1**).

- Deer Mouse: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 1.6 and 4.7 mg/kg, respectively. As the 2,6-DNT NOAEL and LOAEL TRVs are based on blood chemistry and body weight that are non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 2.7 mg/kg for total soil) is selected using the Rule of Five. The NOAEL-EcoPRG from the RSA Study (0.0342 mg/kg) is not appropriate to use as the initial NOAEL value, as it is lower than the food chain model NOAEL-based EcoPRG of 1.4 mg/kg, and when multiple NOAEL-based EcoPRGs are available that are protective of the same, or similar, endpoints, it is appropriate to use the highest NOAEL-based value in applying the Rule of Five (USEPA, 1997a; USACHPPM, 2000).

- Short-Tailed Shrew: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 3.9 and 12 mg/kg, respectively. As the 2,6-DNT NOAEL and LOAEL TRVs are based on blood chemistry and body weight that are non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 6.8 mg/kg for total soil) is selected using the Rule of Five. The NOAEL-EcoPRG from the RSA Study (0.0342 mg/kg) is not appropriate to use as the initial NOAEL value, as it is lower than the food chain model NOAEL-based EcoPRG of 3.9 mg/kg, and when multiple NOAEL-based EcoPRGs are available that are protective of the same, or similar, endpoints, it is appropriate to use the highest NOAEL-based value in applying the Rule of Five (USEPA, 1997a; USACHPPM, 2000).

- Red Fox: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 4.5 and 14 mg/kg, respectively. As the 2,6-DNT NOAEL and LOAEL TRVs are based on blood chemistry and body weight that are non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 7.9 mg/kg for total soil) is selected using the Rule of Five. The NOAEL-EcoPRG from the RSA Study (0.0342 mg/kg) is not appropriate to use as the initial NOAEL value, as it is lower than the food chain model NOAEL-based EcoPRG of 4.5 mg/kg, when multiple NOAEL-based EcoPRGs are available that are protective of the same, or similar, endpoints, it is appropriate to use the highest NOAEL-based value in applying the Rule of Five (USEPA, 1997a; USACHPPM, 2000).

In conclusion, the lowest (most conservative) EcoPRGs for 2,6-DNT are as follows:

- Surface soil (0 to 0.5 feet) EcoPRG = 2.7 mg/kg, based on data from the refined food chain model for the Deer Mouse
- Total soil (0 to 3 feet) EcoPRG = 6.8 mg/kg, based on data from the refined food chain model for the Short-Tailed Shrew

2,4,6-TNT. As eight receptors had EEQs above 1 (**Section 15.7.1**), EcoPRGs are necessary for each receptor separately, and the lowest EcoPRG is recommended for use in making risk management decisions (**Table 16-1**).

- Deer Mouse: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 6.0 and 9.0 mg/kg, respectively. As the 2,4,6-TNT NOAEL and LOAEL TRVs are based on blood chemistry and body weight that are non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 7.3 mg/kg for total soil) is selected using the Rule of Five. No NOAEL-EcoPRG is available from the RSA Study as 2,4,6-TNT was not detected in soil in the RSA study area.
- Short-Tailed Shrew: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 3.8 and 5.7 mg/kg, respectively. As the 2,4,6-TNT NOAEL and LOAEL TRVs are based on blood chemistry and body weight that are non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 4.7 mg/kg for total soil) is selected using the Rule of Five. No NOAEL-EcoPRG is available from the RSA Study as 2,4,6-TNT was not detected in soil in the RSA study area.
- Raccoon: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 11 and 17 mg/kg, respectively. As the 2,4,6-TNT NOAEL and LOAEL TRVs are based on blood chemistry and body weight that are non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 13.7 mg/kg for surface soil) is selected using the Rule of Five. No NOAEL-EcoPRG is available from the RSA Study as 2,4,6-TNT was not detected in soil in the RSA study area.
- Raccoon (Louisiana Black Bear): As this receptor is a surrogate for a listed threatened or endangered species (the Louisiana black bear), the NOAEL-based EcoPRG is 88 mg/kg for surface soil, based on results of the refined food chain model. No

NOAEL-EcoPRG is available from the RSA Study as 2,4,6-TNT was not detected in soil in the RSA study area.

- Red Fox: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 5.6 and 8.4 mg/kg, respectively. As the 2,4,6-TNT NOAEL and LOAEL TRVs are based on blood chemistry and body weight that are non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 6.9 mg/kg for total soil) is selected using the Rule of Five. No NOAEL-EcoPRG is available from the RSA Study as 2,4,6-TNT was not detected in soil in the RSA study area.

- Townsend's Big-Eared Bat: As this receptor is a surrogate for a listed threatened or endangered species (the Rafinesque's big-eared bat), the NOAEL-based EcoPRG is 23 mg/kg for surface soil, based on results of the refined food chain model. No NOAEL-EcoPRG is available from the RSA Study as 2,4,6-TNT was not detected in soil in the RSA study area.

- American Woodcock. NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 1.2 and 31 mg/kg, respectively. As the lead NOAEL and LOAEL TRVs are based on hematological effects and other non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 6.1 mg/kg for surface soil) is selected using the Rule of Five.

- Red-Tailed Hawk. NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 5.2 and 133 mg/kg, respectively. As the lead NOAEL and LOAEL TRVs are based on hematological effects and other non-mortality-related endpoints (**Volume I**, **Table 7-25**) Node 4 (or 26.3 mg/kg for surface soil) is selected using the Rule of Five.

In conclusion, the lowest (most conservative) EcoPRGs for 2,4,6-TNT are as follows:

- Surface soil (0 to 0.5 feet) EcoPRG = 6.1 mg/kg, based on data from the refined food chain model for the American Woodcock

- Total soil (0 to 3 feet) EcoPRG = 4.7 mg/kg, based on data from the refined food chain model for the Short-Tailed Shrew

Dioxin. As five receptors had EEQs above 1 (**Section 15.7.1**), EcoPRGs are necessary for each receptor separately, and the lowest EcoPRG is recommended for use in making risk management decisions (**Table 16-1**). It should be noted that for this exercise, dioxin is the 2,3,7,8-TCDD TEQ concentration, as initially discussed in **Volume I**, **Section 6.1.2.3**.

- Deer Mouse: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 9.7E-7 and 9.7E-6 mg/kg, respectively. As the dioxin NOAEL and LOAEL TRVs are based on the reproduction endpoint (**Volume I**, **Table 7-25**) Node 4 (or 3.1E-6 mg/kg for surface soil) is selected using the Rule of Five (Greenberg and Charters, 2005). If the NOAEL-EcoPRG from the RSA Study is used (7.6E-6), Node 4 is 8.6E-6 mg/kg.

- Short-Tailed Shrew: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 4.2E-7 and 4.2E-6 mg/kg, respectively. As the dioxin NOAEL and LOAEL TRVs are based on the reproduction endpoint (**Volume I**, **Table 7-25**) Node 4 (or 1.3E-6 mg/kg for total soil) is selected using the Rule of Five. If the NOAEL-EcoPRG from the RSA Study is used (7.6E-6), the EcoPRG is 7.6E-6 mg/kg because this concentration is numerically greater than either the NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model.

- Raccoon: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 5.9E-6 and 5.9E-5 mg/kg, respectively. As the dioxin NOAEL and LOAEL TRVs are based on the reproduction endpoint (**Volume I**, **Table 7-25**) Node 4 (or 1.9E-5 mg/kg for surface soil) is selected using the Rule of Five. If the NOAEL-EcoPRG from the RSA Study is used (7.6E-6), Node 4 is 2.1E-5 mg/kg.

- Raccoon (Louisiana Black Bear): As this receptor is a surrogate for a listed threatened or endangered species (the Louisiana black bear), the NOAEL-based EcoPRG is 4.2E-5 mg/kg for surface soil, based on results of the refined food chain model. As the RSA NOAEL (7.6E-6 mg/kg) is lower than the NOAEL-based EcoPRG from the food chain model, it is not appropriate for use.

- American Woodcock: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 5.1E-6 and 5.1E-5 mg/kg, respectively. As the dioxin NOAEL and LOAEL TRVs are based on the reproduction endpoint (**Volume I**, **Table 7-25**) Node 4 (or 1.6E-5 mg/kg for surface soil) is selected using the Rule of Five. The RSA NOAEL, which is based on observations of mammalian species, is not considered as a potential starting point for developing EcoPRGs for avian receptors.

In conclusion, the lowest (most conservative) EcoPRGs for dioxin are as follows:

- Surface soil (0 to 0.5 feet) EcoPRG = 3.1E-6 mg/kg, based on data from the refined food chain model for the Deer Mouse

- Surface soil (0 to 0.5 feet) EcoPRG = 8.6E-6 mg/kg, based on data from the RSA Study (and using the Deer Mouse LOAEL-EcoPRG). However, the RSA study is not used to develop the primary EcoPRG recommended in this BERA (**Section 15.7.1**).

- Total soil (0 to 3 feet) EcoPRG = 1.3E-6 mg/kg, based on data from the refined food chain model for the Short-Tailed Shrew

- Total soil (0 to 3 feet) EcoPRG = 7.6E-6 mg/kg, based on data from the RSA Study (and using the RSA NOAEL as the LOAEL-EcoPRG for the Short-Tailed Shrew). However, the RSA study is not used to develop the primary EcoPRG recommended in this BERA (**Section 15.7.1**).

It should be noted that the site-specific background concentrations for dioxin range from 3.96E-6 to 4.41E-6 mg/kg (**Volume I**, **Appendix F**, Table F-1). Some of the recommended EcoPRGs

(above) are below this background range. Therefore, the recommended primary EcoPRGs default to the lower background concentration (4.0E-6 mg/kg), as follows:

- Surface soil (0 to 0.5 mg/kg) EcoPRG = 4.0E-6 mg/kg
- Total soil (0 to 3 feet) EcoPRG = 4.0E-6 mg/kg

If RSA-based "secondary" EcoPRGs are considered, they would be 8.6E-6 mg/kg for surface soil and 7.6E-6 mg/kg for total soil.

16.1.2 EcoPRG Selection for Final COPECs in Sediment

Estimated NOAEL- and/or LOAEL-based EcoPRGs for sediment were presented in **Section 15.7.2** for the three chemicals in sediment selected as final COPECs based on food chain modeling (i.e., mercury, thallium, and lead). These NOAEL- and LOAEL-based EcoPRGs are used to estimate final EcoPRGs based on the Rule of Five (discussed previously) (Greenberg and Charters, 2005). Food-chain-based EcoPRGs are back-calculated to an EEQ of 1.0 and these back-calculations assume that concentrations at which toxicological responses occur are linearly scaled, which is an assumption that may not be valid for all chemicals (see **Section 15.8.5** for uncertainties associated with this approach and Tannenbaum, et al., 2003a). For listed threatened or endangered surrogate species (i.e., the Raccoon [Louisiana Black Bear]) the Rule of Five is not used, as Texas guidance (TNRCC, 2001) requires the use of the NOAEL-based EcoPRG. It should be noted that no EcoPRGs are required for the Saunders Branch Watershed because no final COPECs in sediment were found to have unacceptable hazard for this area.

Mercury. Only the Bank Swallow had an EEQ above 1 (**Section 15.7.2**). Therefore, an EcoPRG is necessary for only this one receptor (**Table 16-2**).

- Bank Swallow: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 0.19 and 1.9 mg/kg, respectively. As the mercury NOAEL and LOAEL TRVs are based on reproduction (**Volume I**, **Table 7-25**), Node 4 (or 0.6 mg/kg for sediment) is selected using the Rule of Five.

In conclusion, the recommended EcoPRG for mercury is 0.6 mg/kg. It should be noted that the site-specific background concentrations for mercury range from 0.052 to 0.064 mg/kg (**Volume I**, **Appendix F,** Table F-5). The recommended EcoPRG (above) exceeds this background range.

Thallium. As two receptors in three watersheds had EEQs above 1 (**Section 15.7.2**), EcoPRGs are necessary for each receptor separately, and the lowest EcoPRG is recommended for use in making risk management decisions (**Table 16-2**). Because NOAEL- and LOAEL-EcoPRGs were the same for each receptor, regardless of the watershed, EcoPRGs specific to a particular

watershed are not needed. It should also be noted that there are considerable uncertainties associated with these thallium EcoPRGs (**Section 15.8.2**).

- Raccoon: NOAEL- and LOAEL-based EcoPRGs based on the refined food chain model were 0.2 and 2.0 mg/kg, respectively. As the thallium NOAEL and LOAEL TRVs are based on reproduction (**Volume I**, **Table 7-25**), Node 4 (or 0.63 mg/kg for sediment) is selected using the Rule of Five (Greenberg and Charters, 2005).
- Raccoon (Louisiana Black Bear): As this receptor is a surrogate for a listed threatened or endangered species (the Louisiana black bear), the NOAEL-based EcoPRG is 0.36 mg/kg for sediment, based on results of the refined food chain model.

In conclusion, the lowest (most conservative) EcoPRG for thallium is 0.36 mg/kg, based on data from the refined food chain model for the Raccoon (Louisiana Black Bear). It should be noted that the site-specific background concentrations for thallium are not available, as this metal was not detected in background sediment samples (**Volume I**, **Appendix F**, Table F-5). The recommended EcoPRG (0.36 mg/kg), however, is below the range of background sediment sample detection limits (**Section 15.8.2**). In addition, the sediment-to-aquatic invertebrate BAF factor used in the food chain model is an assumed value (because all tissue concentrations were non-detect), and this BAF is highly uncertain. These findings suggest that the thallium EcoPRG should be used with caution, as it is likely unnecessarily restrictive, difficult to delineate, and below background concentrations.

Based on the above considerations, an alternative thallium BAF is recommended for use, as discussed in **Section 15.8.2**. Use of this alternative BAF would increase the thallium EcoPRG by a factor of 2.1, resulting in an alternative EcoPRG of 0.76 mg/kg.

Lead. No food chain model based EcoPRG is required for sediment, as no lead EEQs were above 1 (**Table 15-10**).

As discussed in **Section 15.7.2**, the sediment NOAEL and LOAEL lead concentrations, for direct contact aquatic invertebrate growth hazard, are estimated to be 191 and 246 mg/kg, respectively. Using these data and the Rule of Five, the estimated EcoPRG for lead in sediment would be Node 4, or 217 mg/kg for the aquatic invertebrate growth endpoint, but is lowered to Node 3 or 208, due to uncertainties associated with the sediment toxicity tests (e.g., the unusual number of water changeouts and use of reconstituted overlying water with a hardness of 88 mg/L; see **Section 15.8.1)** (**Table 16-2**).

As also discussed in **Section 15.7.2**, the sediment NOAEL and LOAEL lead concentrations, for direct contact survival hazard, are estimated to be 246 and 352 mg/kg, respectively. Using these data and the Rule of Five, the estimated EcoPRG for lead in sediment would be Node 3 (one node lower than the middle node), or 277 mg/kg for the aquatic invertebrate survival endpoint,

but is lowered to Node 2 or 261 mg/kg, due to uncertainties associated with the sediment toxicity tests (e.g., the unusual number of water changeouts and use of reconstituted overlying water with a hardness of 88 mg/L; see **Section 15.8.1)** (**Table 16-2**). A more restrictive node is selected for the survival endpoint, compared with the growth endpoint discussed in the preceding paragraph, due to the severity of the survival endpoint.

Based on results of the sediment toxicity tests, the recommended EcoPRG for lead in sediment, considering both survival and growth endpoints, is 208 mg/kg, as this value is the lower of the two endpoint EcoPRGs.

16.1.3 Facility-Wide Attainment of EcoPRGs

An important concept to recognize when making risk management decisions is that the media-specific EcoPRGs presented in previous subsections have been developed on a Sub-Area and watershed facility-wide basis, rather than a site-specific basis. Therefore, a demonstration of EcoPRG COPEC attainment that is completed and/or reported in future documents (e.g., feasibility studies [FS]) should also be based on a facility-wide approach. For example, the 2,6-DNT EcoPRG for soil in the Waste Sub-Area was estimated to be 6.8 mg/kg in total soil (0 to 3 feet), based on the most exposed receptor (i.e., the Short-Tailed Shrew). Thus, a remedial option selected for any site within the 486-acre Waste Sub-Area would be most appropriately applied if it reduced the *overall* 2,6-DNT soil exposure from 13.6 mg/kg (the current EPC in total soil; **Volume I**, **Table 6-19**) to the recommended EcoPRG of 6.8 mg/kg. As 2,6-DNT was only detected in 17 percent (i.e., 14 of 84) of the Waste Sub-Area soil samples, and the top six detections were 500, 27, 23, 19, 9.3, and 6.8 mg/kg (ranked from highest to lowest), it is likely that the selected remedial option would only need to address 2,6-DNT detections in total soil above approximately 20 to 25 mg/kg. This is because the resultant sub-area-wide 2,6-DNT EPC in total soil (i.e., the residual COPEC concentration) would likely be less than the EcoPRG of 6.8 mg/kg if a few of the highest concentrations were addressed. Therefore, not every 2,6-DNT detection in soil above the EcoPRG of 6.8 mg/kg in the Waste Sub-Area would necessarily need to be addressed. Because the sub-area and watershed delineations were selected as a spatial organizational scheme to represent both small- and large-range receptor exposure areas, application of the EcoPRGs across the entire sub-area/watershed is appropriate, even for the protection of animals such as the shrew that have relatively small home ranges (see also **Section 8.7** of **Volume I** for additional discussion). If there are any uncertainties associated with the protection of small range receptors, as described in **Section 8.7**, that information will also be reiterated in future FS reports, as appropriate.

Finally, as mentioned previously, attainment of EcoPRGs should be on a depth-specific basis. For example, the 2,6-DNT EcoPRG for soil in the Waste Sub-Area was estimated to be 6.8 mg/kg, which should be applied to total soil (0 to 3 feet) because the most exposed receptor

(i.e., the Short-Tailed Shrew) is an animal that is known to dig subterraneous burrows. Detections of any COPEC below 3 feet are not an ecological concern.

16.1.4 Summary of Final EcoPRGs for Soil and Sediment

Based on the results of the above subsections (summarized in **Tables 16-1** and **16-2**), the following final EcoPRGs are recommended for risk management considerations. It should be noted that secondary EcoPRGs for barium and dioxin, estimated using results from the RSA Study (**Section 15.4**), are not presented in the summary table below, because food-chain based EcoPRGs are recommended as the primary EcoPRGs to be considered in individual site FS reports. However, these secondary EcoPRGs may also be considered in an FS, after evaluation of the primary EcoPRGs. A surface soil EcoPRG is not presented for TNT because its total soil EcoPRG is lower than its surface soil EcoPRG, and any remedial action to address total soil would also address surface soil. Surface soil EcoPRGs are not presented for dioxin because both the surface soil and total soil EcoPRGs are the dioxin background concentration.

COPEC	Sub-Area or Watershed	Depth of Interest (mg/kg)	Final EcoPRG (mg/kg)
Soil			
Barium	Waste Sub-Area	Surface Soil (0 – 0.5) Total Soil (0 – 3)	222 520
Lead	Waste Sub-Area	Surface Soil (0 – 0.5)	441
2,4-DNT	Waste Sub-Area	Total Soil (0 – 3)	12
2,6-DNT	Waste Sub-Area	Surface Soil (0 – 0.5) Total Soil (0 – 3)	2.7 6.8
2,4,6-TNT	Waste Sub-Area	Total Soil (0 – 3)	4.7
Dioxin (2,3,7,8-TCDD TEQ)	Waste Sub-Area	Total Soil (0 – 3)	4E-6
Sediment			
Mercury	Goose Prairie Creek Watershed	Sediment (0 – 1)	0.60
Thallium	Goose Prairie Creek, Harrison Bayou, and Central Creek Watersheds	Sediment (0 – 1)	0.76
Lead	Goose Prairie Creek Cove of Caddo Lake	Sediment (0 – 1)	208

As discussed in **Section 16.1.3**, attainment of these EcoPRGs would be most appropriately demonstrated on a sub-area-wide or watershed-wide basis, not on a site-specific basis.

In order to provide guidance for site-specific FS reports that may be generated for individual LHAAP sites, these recommended EcoPRGs are compared with sub-area specific and watershed specific EPCs (from **Volume I** and for lead from **Section 15.7.1**), as follows:

COPEC	Sub-Area or Watershed	Depth of Interest (mg/kg)	Recommended EcoPRG (mg/kg)	Applicable Receptor	Area EPC (mg/kg)	Potential Ecological Concern? [a]
Soil						
Barium	Waste Sub-Area Waste Sub-Area	0 – 0.5 0 – 3	222 520	Deer Mouse Short Tailed Shrew	1,011 553	Yes Yes
Lead	Waste Sub-Area	0 – 0.5	441	American Woodcock	178	No
2,4,-DNT	Waste Sub-Area	0 – 3	12	Red Fox	101	Yes
2,6-DNT	Waste Sub-Area Waste Sub-Area	0 – 0.5 0 – 3	2.7 6.8	Deer Mouse Short Tailed Shrew	2.4 13.6	No Yes
2,4,6-TNT	Waste Sub-Area	0 – 3	4.7	Short Tailed Shrew	287	Yes
Dioxin (2,3,7,8-TCDD TEQ)	Waste Sub-Area	0 – 3	4E-6	Short Tailed Shrew	3.4E-5	Yes
Sediment						
Mercury	Goose Prairie Creek Watershed	0 – 1	0.60	Bank Swallow	0.265	No
Thallium	Goose Prairie Creek, Harrison Bayou, and Central Creek Watersheds	0 – 1	0.76	Raccoon (Louisiana Black Bear)	0.70, 0.60, 0.70	No [c]
Lead [b]	Goose Prairie Creek Cove of Caddo Lake	0 – 1	208	Aquatic Invertebrate (*H. azteca*)	76.6 (entire watershed) 542 (MDC in Cove)	No Yes

Notes and Abbreviations:

[a] Chemicals whose exposure point concentration (EPC) exceed their EcoPRG are considered to be of potential ecological concern.

[b] Some of the lead in sediment may not be site-related (Section 15.8.4).

[c] Uncertainties associated with the thallium sediment EcoPRG should be considered. The EcoPRG of 0.76 mg/kg is based on the use of an alternative BAF (see Sections 15.8.2 and 16.1.2).

MDC maximum detected concentration

16.2 Summary of Decision Outcomes for Final COPECs

This section presents a summary of the determination that was made in the BERA for all the final COPECs that were identified at the Installation following Step 3.

16.2.1 Soil Final COPECs

Cadmium, chromium, zinc, and perchlorate were the final COPECs evaluated for the Industrial Sub-Area. All of these chemicals were final COPECs due to concerns or uncertainties regarding food chain effects. However, based on the BERA refined food chain models using site-specific data, all of these chemicals had EEQs less than 1 for all receptors (**Section 15.1**). Therefore, no EcoPRGs were developed for any of these chemicals. No unacceptable hazard was identified for any of the final COPECs in the Industrial Sub-Area, and no further action is recommended for chemicals in soil the Industrial Sub-Area based on ecological concerns.

Barium, cadmium, chromium, lead, 2,4-DNT, 2,6-DNT, 2,4,6-TNT, and dioxin were the final COPECs evaluated for the Waste Sub-Area. All of these chemicals were final COPECs due to concerns regarding food chain effects. Based on the BERA refined food chain models using site-specific data, barium, lead, 2,4-DNT, 2,6-DNT, 2,4,6-TNT, and dioxin had EEQs that exceeded 1 for at least one receptor (**Section 15.1**). Further action may be needed for these chemicals in soil in the Waste Sub-Area to address ecological concerns. EcoPRGs were developed for these chemicals (**Section 16.1.1**) to aid in the evaluation of remedial alternatives (**Section 16.3**). The EcoPRG for lead was higher than the EPC in the Waste Sub-Area (**Section 16.1.4**), thus lead is not an ecological concern. In summary, no further action for cadmium, chromium, or lead in soil in the Waste Sub-Area is recommended to address ecological concerns.

No final COPECs were identified in soil in the Low Impact Sub-Area.

16.2.2 Sediment Final COPECs

Lead, mercury, silver, and thallium were the final COPECs evaluated for the Goose Prairie Creek Watershed. Thallium was also a final COPEC in Central Creek and Harrison Bayou. Lead, mercury, and thallium were final COPECs due to concerns regarding food chain effects. Lead, mercury, and silver were selected as final COPECs due to concerns regarding direct toxicity. Based on the BERA refined food chain models using site-specific data, mercury and thallium had EEQs that exceeded 1 for at least one receptor (**Section 15.1**). Sediment toxicity tests suggested that lead (but not mercury or silver) was possibly associated with impaired growth and survival of amphipods in sediment samples collected from the North Goose Prairie Creek Cove of Caddo Lake (**Section 15.2**). Therefore, EcoPRGs were developed for lead, mercury, and thallium (**Section 16.1.2**) for consideration by risk managers. However, the EcoPRG for mercury was higher than the EPC in the Goose Prairie Creek watershed (**Section 16.1.4**), and there is considerable ambiguity as to whether thallium is background-related, and the degree to which it bioaccumulates in aquatic organisms (**Section 15.8.2**). Therefore, no further action for mercury or thallium in sediment is recommended to address ecological concerns. There is also some question as to whether lead is related to historical operations at the Installation (**Section 15.8.4**).

16.3 Other Risk Management Considerations

The BERA is not the only information that the risk manager should consider when evaluating remedial options during the FS phase of the Superfund process. The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (40 Code of Federal Regulations [CFR] 300.430(f)(1)(i)) specifies that each remedial alternative should be evaluated according to nine criteria. Two are considered threshold criteria, and take precedence over the others:

(1) Overall protection of human health and the environment.
(2) Compliance with applicable or relevant and appropriate requirements (ARARs) (unless waiver applicable).

As described in the rest of **Section 16.3** below, a particularly important consideration for the first criterion is the ecological impacts of the remedial options.

Five of the nine criteria are considered primary balancing criteria to be considered after the threshold criteria

(3) Long-term effectiveness and permanence.
(4) Reduction of toxicity, mobility, or volume of hazardous wastes through the use of treatment.
(5) Short-term effectiveness.
(6) Implementability.
(7) Cost.

Finally, two additional criteria are referred to as modifying criteria that must be considered:

(8) State acceptance.
(9) Community acceptance.

Effective risk communication is particularly important to help ensure that a remedial option that best satisfies the other criteria can be implemented at a site. Additional factors that the Risk Manager should take into consideration include existing background levels, current and likely future land uses, current and likely future resource uses in the area, and local, regional, and national ecological significance of the site. Consideration of the ecological impacts of remedial options and residual risks associated with leaving COPECs in place are very important considerations, as described briefly in **Section 16.4**.

16.4 Ecological Impacts of Remedial Options

Management of ecological risks should take into account the potential for impacts to the ecological assessment endpoints from implementation of various remedial options (USEPA, 1997a). The risk manager should balance: (1) residual risks posed by site COPECs before and after implementation of the selected remedy with (2) the potential impacts of the selected remedy on the environment independent of ecological hazards. The selection of a remedial alternative could require tradeoffs between long-term and short-term risk. The ecological risks posed by the "no action" alternative are the risks estimated by the BERA (**Section 15.0**). In addition, each remedial option is likely to have its own ecological impact. This impact could be anything from a short-term loss to complete and permanent loss of the present habitat and ecological communities. In instances where substantial ecological impacts may result from the selected remedy (e.g., dredging the Goose Prairie Creek Cove of Caddo Lake), the risk manager should

consider ways to mitigate the impacts of the remedy and compare the mitigated impacts to the threats posed by the site COPECs. During the FS, the boundaries of potential risk under the no-action alternative (i.e., baseline conditions) are compared with the evaluation of potential impacts of the remedial options to help justify the preferred remedy. The preferred remedy should minimize the risk of long-term impacts that could result from the remedy and any residual contamination. When the selected remedial option leaves some site COPECs in place that are presumed to pose an ecological risk, the justification for the selected remedy should be clearly documented. Consideration of the environmental effects of the remedy itself might result in a decision to allow COPECs to remain on site at levels higher than the thresholds for effect on the assessment endpoint. Thus, selection of the most appropriate ecologically-based remedy can result in residual contamination that presents some risk.

16.5 Scientific Management Decision Point

At the end of Step 8, a SMDP is reached (USEPA, 1997a). The risk management decision is finalized in the Record of Decision. The decision should minimize the risk of long-term impacts that could result from the remedy and any residual COPECs. When the selected remedy leaves residual COPECs at levels higher than the upper-bound estimate of the threshold for adverse effects on the assessment endpoint, the risk manager should justify the decision (e.g., describe how a more complete physical remedy could jeopardize an ecological community more than the residual contamination).

As individual FS reports will be prepared for many of the individual sites at LHAAP, recommended remedial alternatives for each site are not available at the current time. However, the information presented in this BERA report, and the recommended EcoPRGs in **Section 16.1.4**, provide information to assist in reaching risk management decisions.

Dioxin Summary [d]	WSA		SS TS						4E-6 [e] 4E-6 [e]

Notes:

AW	American Woodcock
COPEC	chemical of potential ecological concern
DM	Deer Mouse
EcoPRG	ecological preliminary remediation goal
FCM	food chain model (refined FCM with site-specific BERA inputs; (Note: FCM-based EcoPRGs are considered primary EcoPRGs)
LOAEL	lowest observed adverse effect level
NA	not applicable (see text for discussion)
NOAEL	no observed adverse effect level
RAC	Raccoon
RAC (LBB)	Raccoon (Louisiana Black Bear)
RF	Red Fox
RSA	rodent sperm analysis study (Note: the RSA-based EcoPRGs are considered secondary EcoPRGs)
RTH	Red-Tailed Hawk
RV	toxicity reference value
SS	surface soil (0 to 0.5 feet)
STS	Short-Tailed Shrew
TBEB	Townsend's Big-Eared Bat
TS	total soil (0 to 3 feet)
WSA	waste sub-area

Footnotes:

[a] See text for discussion of the Rule of Five.
[b] The Rule of Five Node (1 through 7) selected based on the TRV endpoint of concern, see text for discussion.
[c] The Final EcoPRG recommended for risk management consideration.
[d] The dioxin EcoPRGs refer to the 2,3,7,8-TCDD TEQ concentration, see text for discussion.
[e] As the site-specific background concentration for dioxin (2,3,7,8-TCDD TEQ concentration) ranges from 3.96E-6 to 4.41E-6 mg/kg, and the recommended EcoPRGs in the table are below this background range (3.1 E-6 and 1.3 E-6 for surface soil and total soil, respectively), the recommended EcoPRGs default to 4.0E-6 for both surface soil and total soil.

Table 16-2
Calculation of Final EcoPRGs for Sediment

Final COPEC	Area	Receptor	NOAEL-Based EcoPRG (mg/kg) (Basis)	LOAEL-Based EcoPRG (mg/kg) (Basis)	Geometric Progression Using the Rule of Five [a] (mg/kg)	TRV Endpoint	Rule of Five Node Selected [b]	Final EcoPRG (mg/kg) [c]
Mercury	GPC	BS	0.19 (FCM)	1.9 (FCM)	0.19, 0.28, 0.41, 0.60, 0.88, 1.3, and 1.9	Reproduction	4	0.60
Mercury Summary	GPC							0.60
Thallium	GPC, HB, CC	RAC	0.20 (FCM)	2.0 (FCM)	0.20, 0.29, 0.43, 0.63, 0.93, 1.4, and 2.0	Reproduction	4	0.63
Thallium	GPC, HB, CC	RAC (LBB)	0.36 (FCM)	NA	NA	Reproduction	1	0.36
Thallium Summary	GPC, HB, CC							0.36 [d]
Lead	GPC Cove	Aquatic Invertebrates	191 (Tox)	246 (Tox)	191, 199, 208, 217, 226, 236, and 246	Growth	3	208
Lead	GPC Cove	Aquatic Invertebrates	246 (Tox)	352 (Tox)	246, 261, 277, 294, 312, 332, and 352	Survival	2	261
Lead Summary	GPC Cove							208

Notes:

BS	Bank Swallow
CC	Central Creek Watershed
COPEC	chemical of potential ecological concern
EcoPRG	ecological preliminary remediation goal
FCM	food chain model (refined FCM using site-specific BERA inputs)
GPC	Goose Prairie Creek Watershed
GPC Cove	GPC Cove of Caddo Lake
HB	Harrison Bayou Watershed
LOAEL	lowest observed adverse effect level
NA	not applicable (see text for discussion)
NOAEL	no observed adverse effect level
RAC	Raccoon
RAC (LBB)	Raccoon (Louisiana Black Bear)
TRV	toxicity reference value
Tox	site-specific toxicity study conducted using LHAAP sediment, see text for discussion.

Footnotes:

[a] See text for discussion of the Rule of Five.

[b] The Rule of Five Node (1 through 7) selected based on the TRV endpoint of concern and other considerations; see text for discussion.

[c] The Final EcoPRG recommended for risk management consideration.

[d] The thallium EcoPRG of 0.36 mg/kg should be used with caution, as it is below the range of background sediment sample detection limits. In addition, the sediment-to-aquatic invertebrate BAF factor used in the food chain model (used to estimate the EcoPRG) is an assumed value, and this BAF is highly uncertain. Thus, the thallium EcoPRG should be used with caution, as it is likely unnecessarily restrictive, difficult to delineate, and below background concentrations. Use of an alternative BAF would result in an increase of the EcoPRG from 0.36 mg/kg to 0.76 mg/kg, see text for discussion.

1.0 INTRODUCTION

Laboratory toxicity and bioaccumulation testing was conducted on freshwater sediments and soils collected from the Longhorn Army Ammunition Plant. The testing program was part of an environmental investigation being conducted by Shaw Environmental & Infrastructure at the Longhorn Army Ammunition Plant site. Three tests were conducted: a 10-day sediment toxicity test with the amphipod *Hyalella azteca*, a 28-day sediment bioaccumulation test using the oligochaete *Lumbriculus variegatus*, and a 28-day soil bioaccumulation test with the lumbricid earthworm *Eisenia fetida*. The *H. azteca* test evaluated the toxicity of sediments to organism survival and growth. The *L. variegatus* and *E. fetida* tests examined the potential for chemicals in the sediments and soils to bioaccumulate in the test organisms. Testing was conducted between October 13 and November 28, 2006 at the Washington Laboratory of Nautilus Environmental located in Tacoma, Washington. Tissue from *L. variegatus* and *E. fetida* were sent to Severn Trent Laboratories at the end of the testing period for analysis of uptake.

2.0 METHODS

2.1 Samples

Sediment and soil sampling was conducted by Shaw Environmental personnel between October 3 to 6, 2006. A total of fourteen sediments and ten soil samples were collected into 4-liter (L) wide-mouthed plastic jars (sediments) or 8-L plastic buckets (soils). The containers were labeled, packed in ice chests containing cubed ice, and shipped by overnight courier service. Seven sediments were from Caddo Lake and seven from Goose Prairie Creek. One of the sediments from each location was identified as reference sediment.

Upon receipt at the Nautilus laboratory, the coolers were opened and the contents verified against information provided on the chain-of-custody forms (COC). Sample temperatures were measured in the temperature blank included in each ice chest and recorded on the COC. Samples were stored at 4 ±1°C in the dark under nitrogen atmosphere prior to test initiation and then archived.

Sediment and soil samples were identified as listed in Table 1. Based on results of chemical analytical testing, eight of the sediment samples were selected by the Client for toxicity and

00059600

bioaccumulation testing. In addition, per instructions from the Client project manager, the two reference sediments were included in the toxicity test but not in the bioaccumulation test.

Checks indicate testing conducted with each sample.

Sediment porewater samples were collected by centrifugation of bulk sediment and were analyzed for total ammonia and sulfides. All but one of the sediment samples contained no interstitial water due to an on-going drought at the project site. Dry sediments were mixed with deionized water (DI), 50% by volume, stirred for an hour, and then centrifuged. The resulting water was analyzed for total ammonia and sulfides.

2.2 Sediment preparation

The pH of overlying water for some of the test sediments was below the accepted lower tolerance for *H. azteca* (Snucins 2003; Grapentine 1992). The pH of the sediments was increased prior to initiating tests by renewing overlying water twice daily until the pH was at least 6.0 units. The methods used to increase the pH for the *H. azteca* and *L. variegatus* tests are described below in their respective sections. In the *H. azteca* test (methods described below) the creek and lake sediments were tested separately because the pH of the Goose Prairie Creek sediments reached acceptable levels more quickly.

2.3 *Hyalella azteca* 10-day survival and growth test

H. azteca were exposed to test sediments for 10 days to determine the effects of site sediment on survival and growth. The tests were conducted according to methods presented in USEPA (2000) and ASTM (2000a), and are summarized in Table 2.

H. azteca were obtained from Aquatic BioSystems (Fort Collins, Colorado). The organisms were transported in coolers in 500-milliliter (mL) plastic containers with oxygen-saturated water and fine screens as a substrate. Upon arrival at the laboratory, water quality parameters were measured and observations of animal condition were made. The organisms were acclimated to test conditions with any observation of stress recorded.

Prior to test initiation, the sediments were homogenized and 50 mL was distributed to labeled test chambers and 175-mL laboratory water was added to each container. The hardness of the laboratory water was modified to match historical hardness of the site (47 mg/L for the creek sediments and 31 mg/L for the lake sediments). Control sediment consisted of clean, washed beach sand obtained from Dash Point, Washington mixed with peat (2% by weight). Overlying water was renewed twice daily to increase the pH to a level within the reported tolerance for *H. azteca*, targeting 6.0 units. The creek sediments stabilized within two days and the test was initiated on October 20, 2006. The lake sediments, however, continued to have unacceptable pH levels. The preparation of lake sediments for testing was, therefore, restarted using laboratory water at a hardness of 88 mg/L to provide more buffering. Bulk sediments from the sample containers were distributed to 20-L buckets, mixed with overlying water, and kept at 4 ±1°C in the dark. Renewal of the overlying water was conducted twice daily until the pH in the sediments reached 6.0 units. The lake sediments were then distributed to 300-mL glass beakers using 50 mL of sediments and 175 mL of laboratory water at a hardness of 88 mg/L.

In both sets of tests, the test chambers were randomized and the sediments were left to settle and equilibrate for 24 hours prior to addition of test organisms. Organisms were carefully separated into groups of 10 amphipods in 30 mL cups containing moderately hard synthetic laboratory water (MHSW). The number of organism was then recounted and any animals exhibiting signs of stress were replaced. The organisms were then gently added to the test chambers, two cups for each test chamber for a total of 20 organisms per chamber (100 organisms per sample location).

Each test chamber was provided 1 mL of food every 2 to 3 days. The food consisted of a mixture of 2.0 grams (g) ground Tetramin® flakes mixed with 100 mL of laboratory water. The feeding regime was reduced if the presence of excess food was observed on the sediment surface in several test chambers.

Overlying water was renewed and temperature, dissolved oxygen (DO), pH, and conductivity were monitored daily before and after renewal for each sample location. Aeration in each test chamber was examined daily to ensure proper airflow. Abnormal conditions or unusual animal behavior, if observed, were also noted daily. Subsamples of overlying water were collected for ammonia and sulfide analyses from each water quality replicate at day 0 and 10 of the test. At test termination, the contents of each test chamber were gently mixed to suspend the sediment and poured through a 0.25-millimeter (mm) Nitex screen. The sediment was rinsed through the screen using dilution water. Animals were removed from the screen into a glass dish and number of survivors counted and recorded. Organisms were then transferred to tared weigh pans, dried in an oven for 24 hours at 60°C, and weighed. The number of surviving amphipods and weight per organism was evaluated statistically to determine whether any samples exhibited a significant decrease in survival or growth relative to the control or reference sediment ($p<0.05$). The criterion for acceptable test performance was ≥80% survival of control organisms.

A reference toxicant test using copper chloride ($CuCl_2$) was conducted in conjunction with the tests on the sediments to determine whether the sensitivity of the test organisms was appropriate based on historical data in the laboratory (see Section 4.0).

Table 2. Summary of test conditions for the 10-d *Hyalella azteca* test.

Test start date	Goose Prairie Creek Sediments: 10/20/2006 Caddo Lake Sediments: 10/23/2006
Test end date	Goose Prairie Creek Sediments: 10/30/2006 Caddo Lake Sediments: 11/2/2006
Test organism	*Hyalella azteca*
Test organism source	Aquatic BioSystems, Fort Collins, CO
Organism age at test initiation	10-12 days
Feeding	1 mL of Tetramin mixture every 2 to 3 days; frequency reduced if excess food observed
Test chamber	300-mL glass beaker
Sediment depth	2 centimeters (approximately 50 mL)
Dilution water type	Synthetic water; varying hardnesses
Dilution water volume	175 mL
Overlying water renewal	70% daily
Control sediment	Washed sand mixed with dried peat (2% by weight)
Number of organisms/replicate	20
Number of replicates/sample	5
Test temperature	23 ± 1°C
Illumination	16 hours light followed by 8 hours dark
Aeration	Continuous, fine bubbles using microtubing
Test acceptance criterion	≥80% survival of control organisms
Reference toxicant	Copper chloride

2.4 *Lumbriculus variegatus* 28-day bioaccumulation exposure to sediments

L. variegatus were exposed to test sediments for 28 days to obtain tissue to measure uptake of specific contaminants. The test was conducted according to procedures presented in USEPA (2000) and ASTM (2000b), and are summarized in Table 3.

Test specimens were obtained from Aquatic Foods (Fresno, California) on October 26, 2006. The organisms were transported in a cooler in plastic bags with sufficient water to keep the animals moist. Upon receipt, the worms were placed in 8-L glass aquaria with gently aerating laboratory water and shredded unbleached paper towels. The tanks were held at 23±1°C and culture water was renewed daily. The *L. variegatus* were fed brine frozen brine shrimp during the culture period.

00059604

Due to the low pH, the sediments were prepared for testing by distributing 4 L of bulk sediment to 20-L buckets and adding laboratory water at a hardness of 88 mg/L. The sediments were placed in the cold room (4 ±1°C, in the dark) and the overlying water was renewed twice daily.

A preliminary 96-hour toxicity-screening test was conducted prior to initiating the 28-day bioaccumulation test and used to determine acute survival of *L. variegatus* in the sample sediments. The screen was conducted with two replicates of each site and the control sediment. Each test chamber consisted of a 300-mL glass beaker containing 100 mL of control or test sediment and 175 mL of overlying laboratory water. The creek sediments were tested with overlying water at a hardness of 47 mg/L and the lake sediments at a hardness of 31 mg/L. Ten individuals were placed in each test chamber. Organisms added to the test chambers were observed to ensure that they were able to burrow into the sediment.

During the 96-hour testing period, chambers were renewed twice daily with laboratory water. Overlying water removed from chambers was analyzed for standard water quality parameters consisting of pH, DO, conductivity, and temperature. In addition, ammonia, alkalinity, and hardness were analyzed on days 0 and 3. The worms were isolated from the sediments at the end of the 96-hour period and counted to determine if numbers of *L. variegatus* were significantly reduced in the test sediment relative to the control sediment.

In the 28-day bioaccumulation test, the organisms were exposed to test sediments to assess the potential for chemicals in the sediments to bioaccumulate in tissue. Test chambers consisted of 8-L glass aquaria placed in an environmental chamber maintained at 23±1°C and set for a photoperiod of 16 hours light and 8 hours dark.

The USEPA protocol recommends a maximum worm tissue-loading rate of 1 g worm tissue per 50 g total organic carbon (TOC) measured on a dry weight basis. A summary of TOC values and maximum recommended worm tissue per replicate test chamber is provided in Table 4. Based on available sediment volume, final tissue requirements and low TOC in some of the sediments, the USEPA-recommended loading capacity rate was exceeded by more than 10 percent for the Goose Prairie Creek sites. The deviation, however, did not appear to negatively impact the performance of the test organisms based on comparable recovery and visual appearance of the condition of the worms.

00059605

The samples were thoroughly homogenized prior to distribution to each of three replicate chambers. Each replicate received one and a half liter of control or sample sediment with laboratory water matching hardness of the site overlying water (47 for creek sediments and 31 for lake sediments). Sediment and overlying water were allowed to settle and equilibrate for 24 hours prior to the addition of test organisms. A subset (15 g) of worms from the test population were collected and frozen in a plastic bag to provide information on background tissue chemistry. Target stocking weight of *L. variegatus* in each chamber was 10 grams. The animals were not fed during the test period.

Renewal of overlying water was conducted twice daily during the test period. Conductivity, pH, DO, and temperature were recorded daily. In addition, ammonia, alkalinity and hardness were checked and recorded on days 0, 7, 14, 21, and 28.

At test termination, animals were isolated by sorting through the sediment in each replicate. As animals were isolated, they were placed in a one-liter jar with laboratory water at the correct hardness and left to complete purging of the gut for at least six hours. Animals from all replicates for each site were pooled during the gut purging time period. After purging, the worms were blotted dry, weighed and placed in a plastic bag for freezing at –20 °C. The next day the frozen worms were packed in a cooler containing dry ice and shipped to the analytical laboratory for tissue analysis. A separate 15 g unexposed tissue sample was sent to the analytical laboratory for % moisture determination, so that chemical results could be reported on a wet weight basis. Bioaccumulation chemical analyses, the primary endpoint of this assay, were provided directly to the client by the analytical laboratory and are not included in this report.

A sediment control (negative control) and a reference toxicant test using copper chloride ($CuCl_2$) (positive control) was conducted in conjunction with the test to ensure that organisms were not impacted by stresses other than contamination in the test material.

00059606

Table 3. Summary of test conditions for the 28-d bioaccumulation test with *Lumbriculus variegatus*.

Test start date	10/31/2006
Test end date	11/28/2006
Test organism	*Lumbriculus variegatus*
Test organism source	Aquatic Foods, Inc., Fresno, CA
Feeding	None
Test chamber	8-L glass aquaria
Test sediment volume	1.5 L
Dilution water type & volume	4-liter laboratory water at hardness of test site
Overlying water renewal	50% twice daily
Control sediment	Washed sand mixed with peat (8% by weight)
Wet weight of organisms per chamber	~10 g
Number of replicates/sample	3
Test temperature	23 ± 1°C
Illumination	16 hours light followed by 8 hours dark
Aeration	Continuous, approximately 100 bubbles/minute
Reference toxicant	Copper chloride

Table 4. Recommended maximum Lumbriculus loading rates based on sediment total organic carbon content.

Sample ID	Percent TOC (dry weight)	Dry weight TOC per replicate (g)[a]	Max. wet weight of worms (g)[b,c]
IWSD06-BERA-SD06	0.80	16.3	**2.3**
GPWSD03-BERA-SD07	0.83	17.0	**2.4**
GPWSD02-BERA-SD11	3.18	65.1	9.3
CL-GPSN-2-BERA-SD09	6.29	128.8	18.4
CL-GPSN-3-BERA-SD02	4.37	89.5	12.8
CL-GPSN-4-BERA-SD01	5.92	121.2	17.3
CL-GPSS-2-BERA-SD04	4.62	94.6	13.5
CL-GPSS-3-BERA-SD10	5.18	106.1	15.1

[a] Weight TOC is based on a total of 1.5L of sediment per replicate with a mean total dry weight of 2048 g.
[b] Calculated based on the USEPA-recommended tissue loading rate of 1 g tissue per 50 g TOC (dry weight).
[c] Tissue wet weight values were calculated using a dry/wet weight conversion of 14 percent (i.e. worms were approximately 86 percent water).
Bold values indicate sites where final worm additions (10 g wet weight per replicate exceeded the recommended USEPA criteria by a substantial margin (>10%) based on TOC.

00059607

2.5 *Eisenia fetida* 28-day bioaccumulation exposure to soils

E. fetida were exposed to test soils for 28 days to obtain tissue to assess the potential for chemicals in the soils to bioaccumulate in tissue. The test was conducted according to procedures presented in ASTM (1998), and are summarized in Table 5.

Test specimens were obtained from Yelm Earthworm & Castings Farm (Yelm, Washington) on October 12, 2006. The earthworms were transported in a box in mesh bags containing a small amount of moist soil. Upon receipt, the worms were placed in 8-L glass aquaria and kept moist. The tanks were held at 20±1°C and monitored daily.

Test chambers consisted of one-liter glass jars with perforated lids to allow air exchange. The test chambers were placed in an environmental chamber maintained at 20 ±1°C under constant light. Ten replicates were included per site with one additional replicate used for soil quality parameter measurements at points during the test period.

The samples were thoroughly homogenized and sieved through a 6.3 millimeter (mm) stainless steel screen prior to distribution to each replicate chamber. Each test chamber received 200 g dry weight of soil. The percent moisture of each test soil was calculated and used to determine the wet weight of sample to add to provide 200 g dry weight per test chamber. Sufficient volumes of DI water were added to hydrate the soils to an appropriate moisture level. Due to the differences in soil composition (i.e., texture, structure, and organic content), hydrating soils to a standard level can be problematic. One soil may appear very wet and even have standing water on the surface, while another may appear considerably drier after both being hydrated to the recommended hydration level of 35 to 45 percent of its dry weight. To address such differences, an alternative method is to use the artificial control soil hydrated to 45 percent of its dry weight as a standard. All sites were then hydrated to a level approximating the texture and visual appearance of the hydrated artificial soil control. A summary of hydration levels achieved in the test soils is provided in Table 6.

Soils were allowed to settle and the system was left to equilibrate for 24 hours prior to addition of the test organisms. Thirty worms were randomly added to each test chamber after confirmation that the correct number of test organisms was segregated and in healthy condition. The worms were not fed during the test period.

The temperature of the test chambers was monitored daily. Abnormal conditions or unusual animal behavior, if observed, were also noted at this time. Midway through the test, on day 14, a 35g subsample of each soil sample was removed from the surrogate test chambers to check moisture content, pH, and conductivity. Test chambers were kept hydrated with DI water by gently spraying over the surface in each container as needed.

A soil control (negative control) and a 2-chloroacetammide reference toxicant test (positive control) were conducted in conjunction with the test soils to ensure that organisms were not impacted by stresses other than contamination in the test material.

At test termination, each replicate was emptied into a glass dish and gently sorted. Surviving worms were rinsed in DI water and placed in a cup with moist unbleached paper towels to purge. Dead worms were removed and discarded. Surviving worms were purged for 24 hours in a 20 ±1°C environmental chamber with continuous light. After purging, replicates from each site were combined; the worms were then weighed and placed in plastic bags for freezing. Per project specifications, 15g of tissue from each sample location was sent to one analytical laboratory and 5 g of tissue went to another laboratory. The worms were divided before freezing at -20°C. The next day, the frozen earthworms were packed in coolers containing dry ice and shipped to the analytical laboratories by overnight courier service. Bioaccumulation chemical analyses, the primary endpoint of this assay, were provided directly to the client by the analytical laboratory and are not included in this report.

2.6 Statistical Analyses

Statistical analyses were performed for the *H. azteca* tests using Comprehensive Environmental Toxicity Information System Software (CETIS), Version 1.025B. A One-Way Analysis of Variance (ANOVA) using Dunnett's Multiple Comparison Test was performed to determine if significant differences existed among sites for mean survival and growth endpoints. Multiple comparison procedures using t-tests were used to assess differences between individual sites and the control and reference sites. Prior to the analysis, differences in variance were evaluated using Bartlett's Test and evaluation of normal distribution was assessed using Shapiro-Wilk W Test. Survival data, expressed as a percentage, was arcsine square-root transformed prior to analysis to normalize the distribution of the data and satisfy statistical assumptions for analysis. Growth data was not transformed prior to analysis.

Spearman Karber analysis was used to calculate the median lethal concentration (LC_{50}) value and associated confidence intervals fro reference toxicant tests using CETIS or ToxCalc Comprehensive Toxicity Data Analysis and Database Software, Version 5.0.

00059610

3.0 RESULTS

3.1 *Hyalella azteca*

Results of toxicity tests conducted using *H. azteca* are provided in Tables 7 through 10. Results for the Goose Prairie Creek sediments are in Tables 7 and 8 for survival and growth, respectively. Caddo Lake sediments test results are provided in Tables 9 and 10. The tables show mean percent survival, mean growth, as well as results of the statistical analyses comparing response in the sample locations to the control and reference sediments. Detailed results of the sediment toxicity tests, water quality measurements recorded during the tests, and the reference toxicant test results are provided in Attachments A, B and C, respectively. Copies of the chain-of-custody forms are in Attachment D.

Mean survival in the sediment control in both tests exceeded the recommended EPA guidance survival control criterion of 80 percent, with 98 and 95 percent control survival in the creek and lake sediment tests, respectively. Mean survival in the reference sediments was 96 percent for BKG-SD04-BERA-REFSD-01 (Goose Prairie Creek reference sediment) and 87 percent for BKG-CL-SD12-BERA REFSD-02 (Caddo Lake reference sediment).

None of the Goose Prairie Creek sediments exhibited an effect on *H. azteca* survival compared to the control or reference sediment. All three of the creek sediments as well as the reference sediment had reduced growth compared to growth in the control sediment. None of the site sediments, however, showed a statistically significant reduction in growth compared to the creek reference sediment. In fact, growth in the site sediments was greater than that in the creek reference sediment.

One of the Caddo Lake sediments, CL-GPSN-3-BERA-SD02, demonstrated reduced amphipod survival and growth compared to results in both the control and lake reference sediment and also had a relative percent difference (RPD) in response greater than 20 percent. The test sample location, CL-GPSN-2-BERA-SD09, demonstrated a statistically significant difference in growth compared to the control and reference sediment but not in survival. In addition, the RPD was greater than 20 percent for both growth comparisons. Growth in sample location CL-GPSS-3-BERA-SD10 was statistically significantly reduced compared to control results but not to reference sediment results.

Table 7. Survival data for the *Hyalella azteca* test – Goose Prairie Creek Sediments

Sample ID	Percent Survival (Mean ± SD)	Control vs. Sample Locations p-values	Control vs. Sample Locations RPD	BKG-SD04-REFSD vs. Sample Locations p-values	BKG-SD04-REFSD vs. Sample Locations RPD

00059613

3.2 *Lumbriculus variegatus*

No toxicity was observed to *L. variegatus* by any of the test sediments during the short-term screen. Results are shown in Table 11 and are also provided in Attachment B. The 28-day test of bioaccumulation, therefore, proceeded with all eight test sample locations. Sufficient tissue was obtained from all sample locations at the end of the 28-day exposure. Water quality parameters measured during the exposure period and reference toxicant test data are provided in Attachments B and C.

L. variegatus appeared healthy at the end of the 28-day exposure in all samples tested based on visual color and activity. Burrowing, with the anterior portion buried and the posterior portion undulating in overlying water for respiratory exchange, was observed in all samples throughout the duration of the test.

3.3 *Eisenia fetida*

In addition to the collection of tissue for measuring bioaccumulation of chemicals in *Eisenia fetida* exposed to test soils, survival was evaluated at the end of the 28-day exposure. Table 12 shows survival after 28 days of exposure. Mean survival in all sample locations was greater than the control, which had 94 percent survival. A summary of survival and soil quality parameters measured during the 28-day test period are provided in Attachment B.

Table 12. Survival data for the *Eisenia fetida* test

Sample ID	Percent Survival (Mean ± SD)

17SB04-BERA-SS10	97.3 ± 6.4

4.0 QA/QC

The *Hyalella azteca* tests met acceptability criteria for control performance with greater than 80 percent mean control survival and the *Lumbriculus variegatus* and *Eisenia fetida* tests provided sufficient tissue for the analyses required by the project.

As discussed previously, the pH for some of the sediments when initially prepared for testing were below literature values reported as tolerable by *H. azteca*. The pH of the sediments was increased by conducting twice-daily renewal of overlying water until the pH in the sediments was above 6.0 units. This required numerous water changes for some of the sediments resulting in loss of fine grain particles during the process. It should be noted, however, that water change are allowed by the test method. Once the pH was increased to values acceptable for testing, water quality parameters in overlying water remained at acceptable levels throughout the 10-day *H. azteca* tests.

00059615

A few of the sediments continued to have low pH values (i.e., <6.0 units) during the 28-day test of bioaccumulation using *L. variegatus*. This may have been due to use of site-specific hardness in the overlying water providing less buffering capacity in the test chambers. The *L. variegatus* appeared healthy throughout the test period and no obvious mortality (e.g., discolored organisms lying on the sediment surface) was observed during the test period. The soil quality parameters measured during the 28-day exposure in the *E. fetida* test were within ranges defined as acceptable by the protocol.

The recommended organism-loading rate was exceeded for *L. variegatus* based on TOC in two of the sediment samples by more than 10 percent. The USEPA test protocol specifies a recommended maximum loading rate of approximately 1 g dry weight worm tissue to 50 g sediment TOC. The TOC requirement is intended to minimize potential depletion of sediment contaminants and ensure that enough food is available for the test organisms over the duration of the 28-day exposure. The worm/TOC loading rate for IWSDO6-BERA-SD06 and GPWSD03-BERA-SD07 was exceeded by more than 400 percent in two samples due to a combination of low TOC in those sediments and the volume of sediment available for testing. The sediment volume was lower than expected due to the procedures used to increase the pH of the sediments. To ensure that sufficient tissue would be recovered from all sites for chemical analysis, and for consistency, an equal wet weight of worms (10 g) was added to all replicates knowing that the target maximum worm tissue/TOC ratio specified by USEPA was not achieved in two of the samples. Despite exceeding the recommended loading rate, *L. variegatus* in both sample locations with low TOC appeared healthy at the end of the exposure based on their bright color, activity, and abundance. The health of the organisms did not appear, therefore, to have been compromised and it is unlikely that potential contaminants associated with TOC would have been depleted, as the worms appeared to have a source of food throughout the exposure.

00059616

Results of reference toxicant tests conducted with the test organisms are provided in Table 13. Two results are recorded for *Hyalella azteca* because separate batches of amphipods were used for the toxicity testing of the Goose Prairie Creek and Caddo Lake sediments and a reference toxicant test was conducted with organisms from each batch. Mean EC50 results for all tests fell within the acceptable range of mean ± two standard deviations for historical data generated by this laboratory. Thus, these data indicate that the test organisms appeared to have been of an appropriate degree of sensitivity.

Table 13. Reference toxicant test results.

Species	Date Initiated	Toxicant	EC50	95% Confidence Interval	Historical range (mean ± 2 SD)
H. azteca 96h survival	10/20/2006	Copper	504 µg/L	435 - 582	100 - 595
	11/2/2006	Copper	576 µg/L	468 – 710	
L. variegatus 96h survival	11/3/2006	Copper	170 µg/L	139 – 209	68.2 – 188
E. fetida 14d survival	10/19/2006	2-chloroacetamide	28.8 mg/kg	25.9 – 31.9	20.8 – 40.0

Note: Site BKG CL SD12 is a reference sediment site.
NA-not applicable. Test results greater than control or reference sediment results.
Statistical analyses was an equal variance t-test
Shading signifies a statistically signficant difference with 95% confidence and a relative percent difference greater than 20%.

	EEQ N	EEQ L
Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ:	1.1E-06	4.3E-07
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	2.0E-04	4.0E-05
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	5.8E-03	5.8E-04
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	1.3E-04	1.3E-05
Aldrin/Dieldrin/Endrin EEQ:	1.7E-02	1.7E-03

Intake Equation:

$$Ej = \left(\frac{A}{HR}\left[\sum_{i=1}^{m}\left(\frac{IRi\,x\,Cij}{BW}\right)\right]\right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applicable/Not available
BAF (or BCF) values from appropriate text tables (BCF = bioconcentration factor)
Some BAF (or BCF) values based on media regression equations (value in box): [n] See appropriate text tables for equations.
If BAF/BCF regression equation produced Tier 2 value exceeding maximum Tier 1 BAF/BCF value, Tier 1 value used a default.
LOAEL and NOAEL values from appropriate toxicity summary tables in the text.
UF = Uncertainty Factor for toxicity factor extrapolation, and Adjusted LOAEL or NOAEL = LOAEL/UF or NOAEL/UF
A "0" entry in the exposure concentration column indicates this chemical not selected as a COPEC for this medium.
Receptor diet data and home range data from appropriate text table.
Exposure point concentrations (EPCs) from appropriate text tables.

Species-Specific Factors

Factor	Value	Units
Terrestrial plant diet fraction =	0.1	unitless
Aquatic plant diet fraction =	0.45	unitless
Plant root diet fraction =	0.45	unitless
Fish diet fraction =	0	unitless
Aq. Invert diet fraction =	0	unitless
Terr. Invert diet fraction =	0	unitless
Mammal diet fraction =	0	unitless
Bird diet fraction =	0	unitless
Soil ingestion rate =	0	kg/d
Sediment ingestion rate =	0.0080934	kg/d
Food ingestion rate =	0.0861	kg/d
Body weight =	1.174	kg
Home range =	0.1186101	acres
Water intake rate =	0.114	L/d
Site Area =	246	acres
Area Use Factor (AUF) =	1	unitless
Exposure Duration (ED) =	1	unitless

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ:	0.0E+00	0.0E+00
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	0.0E+00	0.0E+00
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	0.0E+00	0.0E+00
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	0.0E+00	0.0E+00

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x \, Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applicable/Not available
BAF (or BCF) values from appropriate text tables (BCF = bioconcentration factor)
Some BAF (or BCF) values based on media regression equations (value in box): n See appropriate text tables for equations.
If BAF/BCF regression equation produced Tier 2 value exceeding maximum Tier 1 BAF/BCF value, Tier 1 value used a default.
LOAEL and NOAEL values from appropriate toxicity summary tables in the text.
UF = Uncertainty Factor for toxicity factor extrapolation, and Adjusted LOAEL or NOAEL = LOAEL/UF or NOAEL/UF
A "0" entry in the exposure concentration column indicates this chemical not selected as a COPEC for this medium.
Receptor diet data and home range data from appropriate text table.
Exposure point concentrations (EPCs) from appropriate text tables.

Species-Specific Factors

Terrestrial plant diet fraction =	0	unitless
Aquatic plant diet fraction =	0.35	unitless
Plant root diet fraction =	0	unitless
Fish diet fraction =	0.55	unitless
Aq. Invert diet fraction =	0.05	unitless
Terr. Invert diet fraction =	0	unitless
Mammal diet fraction =	0	unitless
Bird diet fraction =	0	unitless
Soil ingestion rate =	0	kg/d
Sediment ingestion rate =	0.0008891	kg/d
Food ingestion rate =	0.0178	kg/d
Body weight =	5.6	kg
Home range =	0.5930505	acres
Water intake rate =	0.112	L/d
Site Area =	246	acres
Area Use Factor (AUF) =	1	unitless
Exposure Duration (ED) =	1	unitless

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ:	0.0E+00	0.0E+00
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	0.0E+00	0.0E+00
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	0.0E+00	0.0E+00
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	0.0E+00	0.0E+00

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x \, Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applicable/Not available
BAF (or BCF) values from appropriate text tables (BCF = bioconcentration factor)
Some BAF (or BCF) values based on media regression equations (value in box): n See appropriate text tables for equations.
If BAF/BCF regression equation produced Tier 2 value exceeding maximum Tier 1 BAF/BCF value, Tier 1 value used a default.
LOAEL and NOAEL values from appropriate toxicity summary tables in the text.
UF = Uncertainty Factor for toxicity factor extrapolation, and Adjusted LOAEL or NOAEL = LOAEL/UF or NOAEL/UF
A "0" entry in the exposure concentration column indicates this chemical not selected as a COPEC for this medium.
Receptor diet data and home range data from appropriate text table.
Exposure point concentrations (EPCs) from appropriate text tables.

Species-Specific Factors

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ:	4.6E-04	9.4E-05
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	3.4E-01	3.4E-02
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	3.0E-01	3.0E-02
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	5.2E-03	1.7E-03
Aldrin/Dieldrin/Endrin EEQ:	1.0E-02	3.4E-03

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applicable/Not available
BAF (

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ:	4.1E-03	8.6E-04
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	2.9E+00	2.9E-01
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	4.1E-01	4.4E-02
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	1.3E-03	4.3E-04
Aldrin/Dieldrin/Endrin EEQ:	5.2E-03	1.7E-03

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applicable/Not available
BAF (or BCF) values from appropriate text tables (BCF = bioconcentration factor)
Some BAF (

Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	4.2E+00	1.4E+00
Aldrin/Dieldrin/Endrin EEQ:	4.2E-03	1.4E-03

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x \, Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Clj = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ:	0.0E+00	0.0E+00
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	6.2E-03	6.2E-04
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	2.7E-03	2.7E-04
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	1.5E-01	5.0E-02
Aldrin/Dieldrin/Endrin EEQ:	4.8E-04	1.6E-04

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applicable/Not available
BAF (or BCF) values from appropriate text tables (BCF = bioconcentration factor)
Some B

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ:	1.6E-04	3.3E-05
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	1.1E-01	1.1E-02
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	1.2E-02	1.3E-03
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	2.7E-01	8.9E-02
Aldrin/Dieldrin/Endrin EEQ:	1.2E-03	1.4E-04

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x \, Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applic

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ:	7.4E-05	1.5E-05
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	5.2E-02	5.2E-03
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	6.3E-03	7.0E-04
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	7.3E-02	2.4E-02
Aldrin/Dieldrin/Endrin EEQ:	9.9E-04	1.2E-04

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not appl

Aldrin/Dieldrin/Endrin EEQ:	2.1E-02	2.7E-03

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x \, Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ	1.5E-03	4.2E-04
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	1.1E-02	2.2E-03
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	4.2E-01	4.2E-02
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	1.0E-02	1.3E-03

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x \, Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 =

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1

	EEQ N	EEQ L
Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ	3.5E-04	1.2E-04
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	2.6E-03	5.2E-04
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	9.0E-02	8.9E-03
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	2.5E-03	3.0E-04

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi\,x\,Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applicable/Not available
BAF (or BCF) values from appropriate text tables (BCF = bioconcentration factor)
Some BAF (or BCF) values based on media regression equations (value in box): n See appropriate text tables for equations.
If BAF/BCF regression equation produced Tier 2 value exceeding maximum Tier 1 BAF/BCF value, Tier 1 value used a default.
LOAEL and NOAEL values from appropriate toxicity summary tables in the text.
UF = Uncertainty Factor for toxicity factor extrapolation, and Adjusted LOAEL or NOAEL = LOAEL/UF or NOAEL/UF
A "0" entry in the exposure concentration column indicates this chemical not selected as a COPEC for this medium.
Receptor diet data and home range data from appropriate text table.
Exposure point concentrations (EPCs) from appropriate text tables.

Species-Specific Factors

Factor	Value	Units
Terrestrial plant diet fraction =	0.6	unitless
Aquatic plant diet fraction =	0	unitless
Plant root diet fraction =	0	unitless
Fish diet fraction =	0.05	unitless
Aq. Invert diet fraction =	0.15	unitless
Terr. Invert diet fraction =	0.15	unitless
Mammal diet fraction =	0.05	unitless
Bird diet fraction =	0	unitless
Soil ingestion rate =	0.002394	kg/d
Sediment ingestion rate =	0.002394	kg/d
Food ingestion rate =	0.171	kg/d
Body weight =	5.78	kg
Home range =	2011	acres
Water intake rate =	0.476	L/d
Site Area =	2330	acres
Area Use Factor (AUF) =	1	unitless
Exposure Duration (ED) =	1	unitless

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (l) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound E

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ	2.8E-03	7.7E-04
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	2.4E-02	4.7E-03
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	9.4E-01	9.4E-02
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	8.5E-02	9.3E-03

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ	1.9E-04	5.8E-05
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	1.7E-03	3.4E-04
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	6.5E-02	6.4E-03
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	5.7E-03	6.4E-04

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = E

Table O-36
BERA Tier 2 Chemicals of Potential Concern

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ	9.2E-05	2.5E-05
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	8.1E-04	1.6E-04
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	2.9E-02	2.9E-03
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	2.8E-03	3.1E-04

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using m

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ	1.1E-06	4.3E-07
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	1.1E-04	2.2E-05
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	1.9E-04	1.9E-05
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	2.0E-04	2.0E-05

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, av

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ	2.7E-07	7.1E-08
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	1.9E-05	3.9E-06
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	2.4E-05	2.4E-06
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	3.4E-06	3.7E-07

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg B

Table O-39
BERA Tier 1 Chemicals of Potential Concern

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th perc

Table O-41
BERA Tier 1 Chemicals of Potential Concern
EEQs and Hazard Indices for the Deer Mouse at the LHAAP
Industrial Sub-Area/Central Creek Watershed

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x \, Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using

Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	2.1E-05	2.2E-06

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \times Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 =

Nitrotoluenes (2,4-DNT, 2,6-DNT, TNT) EEQ:	0.0E+00	0.0E+00
Chlordane-like chemicals (alpha/gamma chlordane, cis/trans nonachlor, heptachlor, oxychlordane) EEQ	0.0E+00	0.0E+00
DDX (4,4'-DDD, -DDE, -DDT) EEQ:	0.0E+00	0.0E+00
Aroclors (Aroclor 1242, 1248, 1254, 1260, 1268) EEQ:	0.0E+00	0.0E+00
Phthalates (bis-2ethylhexyl and butylbenzyl) EEQ:	0.0E+00	0.0E+00
Aldrin/Dieldrin/Endrin EEQ:	0.0E+00	0.0E+00

Intake Equation:

$$Ej = \left(\frac{A}{HR} \left[\sum_{i=1}^{m} \left(\frac{IRi \, x Cij}{BW} \right) \right] \right)$$

Where:
Ej = Total Exposure to Chemical
A = Site Area
HR = Home Range
m = Total number of ingested media
i = counter
IRi = Consumption Rate for Medium
Cij = Chemical concentration (j) in medium (I) (mg/kg or mg/L)
BW = Body Weight

Notes:
Tier 1 = Upper-bound EEQ using 95% UCL, upper-bound BAF/BCF (e.g., 90th percentile), avg food intake rates, avg BW, and min home range.
Tier 2 = EEQ using mean EPC, avg BAF/BCF, avg food intake rate, avg BW, and mean home range.
BAF = Bioaccumulation Factor (may be BCF if this is the only value available)
EED = Estimated Exposure Dose
EEQ = Ecological Effects Quotient.
L = LOAEL based; N = NOAEL based
LOAEL = Lowest Observed Adverse Effect Level
mg/kg = milligrams per kilogram
mg/L = milligrams per liter
NOAEL = No Observed Adverse Effect Level
NA = Not applicable/Not available
BAF (or BCF) values from appropriate text tables (BCF = bioconcentration factor)
Some BAF (or BCF) values based on media regression equations (value in box): n See appropriate text tables for equations.
If BAF/BCF regression equation produced Tier 2 value exceeding maximum Tier 1 BAF/BCF value, Tier 1 value used a default.
LOAEL and NOAEL values from appropriate toxicity summary tables in the text.
UF = Uncertainty Factor for toxicity factor extrapolation, and Adjusted LOAEL or NOAEL = LOAEL/UF or NOAEL/UF
A "0" entry in the exposure concentration column indicates this chemical not selected as a COPEC for this medium.
Receptor diet data and home range data from appropriate text table.
Exposure point concentrations (EPCs) from appropriate text tables.

Species-Specific Factors

Terrestrial plant diet fraction =	0	unitless
Aquatic plant diet fraction =	0.35	unitless
Plant root diet fraction =	0	unitless
Fish diet fraction =	0.55	unitless
Aq. Invert diet fraction =	0.05	unitless
Terr. Invert diet fraction =	0	unitless
Mammal diet fraction =	0	unitless
Bird diet fraction =	0	unitless
Soil ingestion rate =	0	kg/d
Sediment ingestion rate =	0.0008891	kg/d
Food ingestion rate =	0.0178	kg/d
Body weight =	5.6	kg
Home range =	0.5930505	acres
Water intake rate =	0.112	L/d
Site Area =	262	acres
Area Use Factor (AUF) =	1	unitless
Exposure Duration (ED) =	1	unitless
